

Machine Learning in Computer Vision

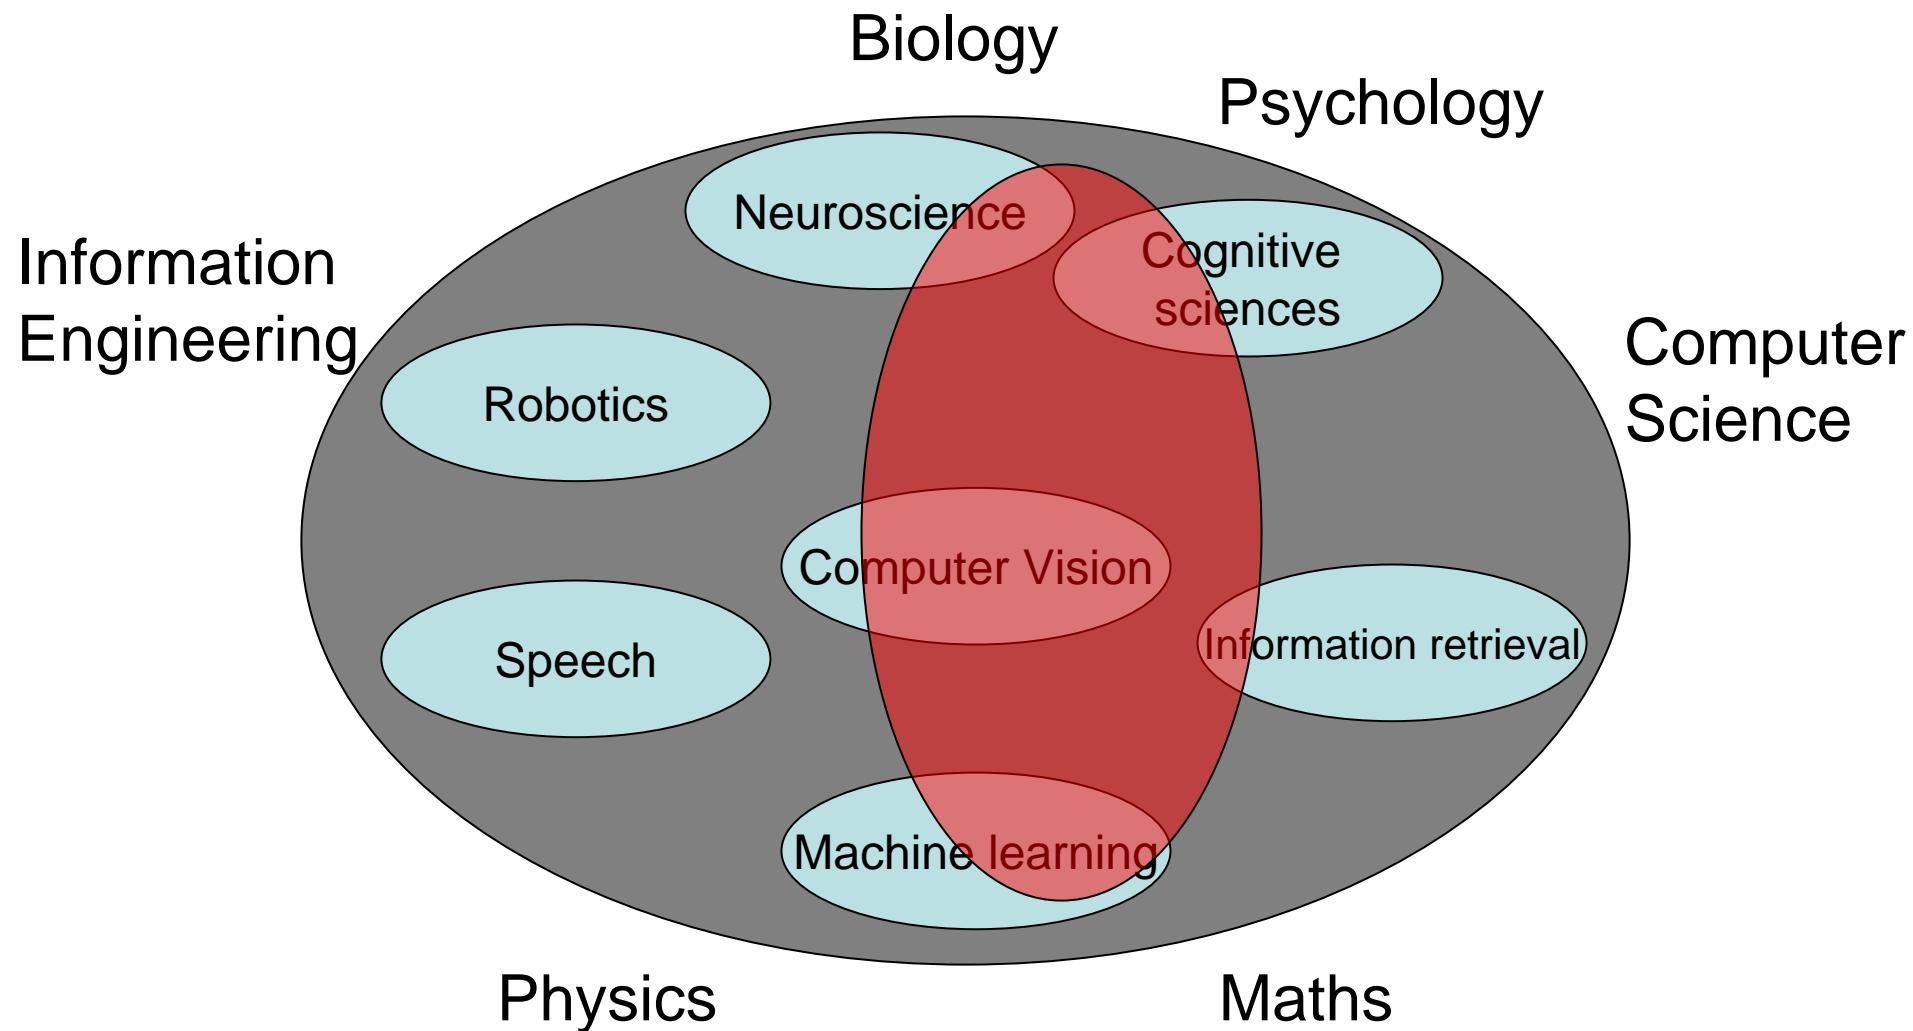

Fei-Fei Li

What is (computer) vision?

- When we “see” something, what does it involve?
- Take a picture with a camera, it is just a bunch of colored dots (pixels)
- Want to make computers understand images
- Looks easy, but not really...

What is it related to?

Quiz?

What about this?

A picture is worth a thousand words.
--- Confucius
or *Printers' Ink* Ad (1921)

Today: machine learning methods for object recognition

outline

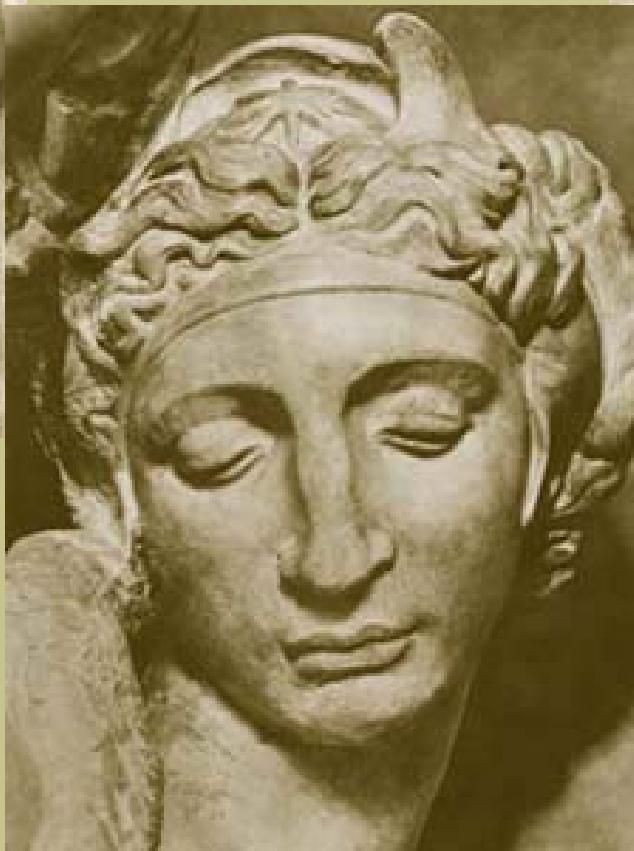

- Intro to object categorization
- Brief overview
 - Generative
 - Discriminative
- Generative models
- Discriminative models

How many object categories are there?

Biederman 1987

Challenges 1: view point variation

Michelangelo 1475-1564

Challenges 2: illumination

slide credit: S. Ullman

Challenges 3: occlusion

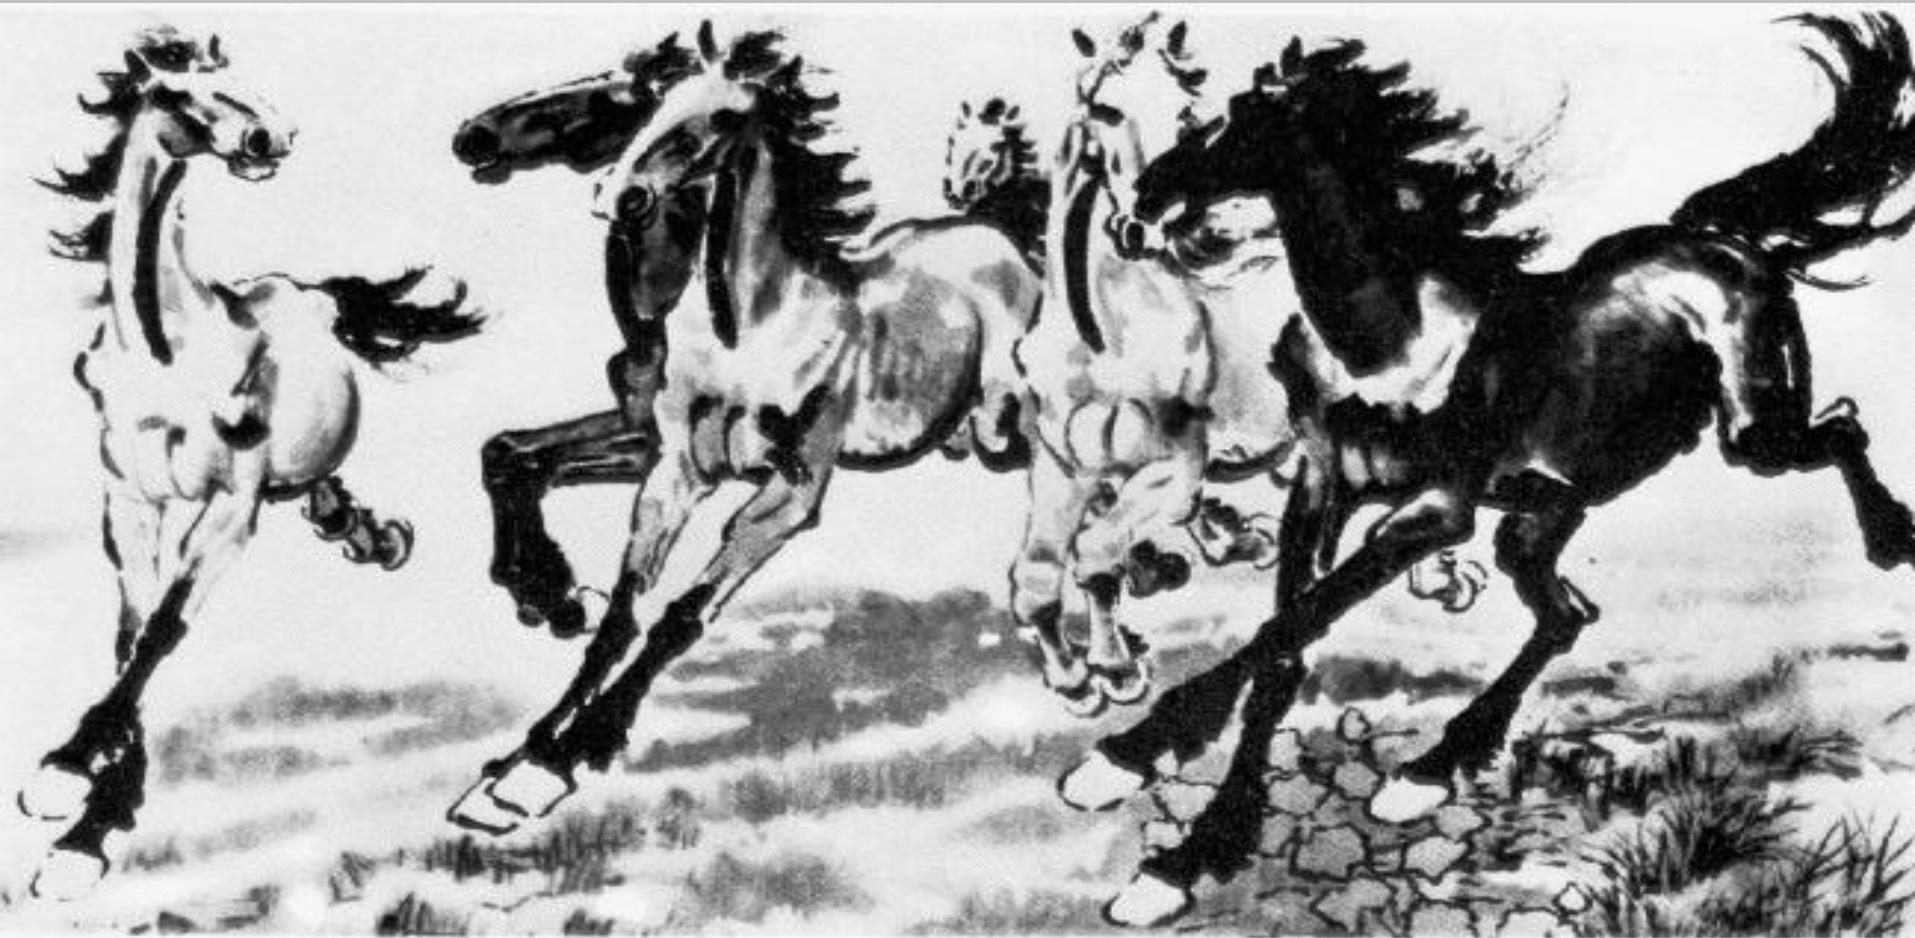

Magritte, 1957

Challenges 4: scale

Challenges 5: deformation

Xu, Beihong 1943

Challenges 6: background clutter

Klimt, 1913

History: single object recognition

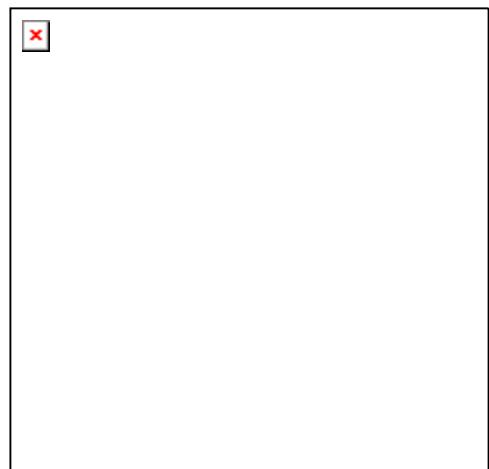

History: single object recognition

- Lowe, et al. 1999, 2003
- Mahamud and Herbert, 2000
- Ferrari, Tuytelaars, and Van Gool, 2004
- Rothganger, Lazebnik, and Ponce, 2004
- Moreels and Perona, 2005
- ...

Challenges 7: intra-class variation

Object categorization: the statistical viewpoint

$p(\text{zebra} \mid \text{image})$

vs.

$p(\text{no zebra}/\text{image})$

- Bayes rule:

$$\frac{p(\text{zebra} \mid \text{image})}{p(\text{no zebra} \mid \text{image})} = \underbrace{\frac{p(\text{image} \mid \text{zebra})}{p(\text{image} \mid \text{no zebra})}}_{\text{posterior ratio}} \cdot \underbrace{\frac{p(\text{zebra})}{p(\text{no zebra})}}_{\text{prior ratio}}$$

Object categorization: the statistical viewpoint

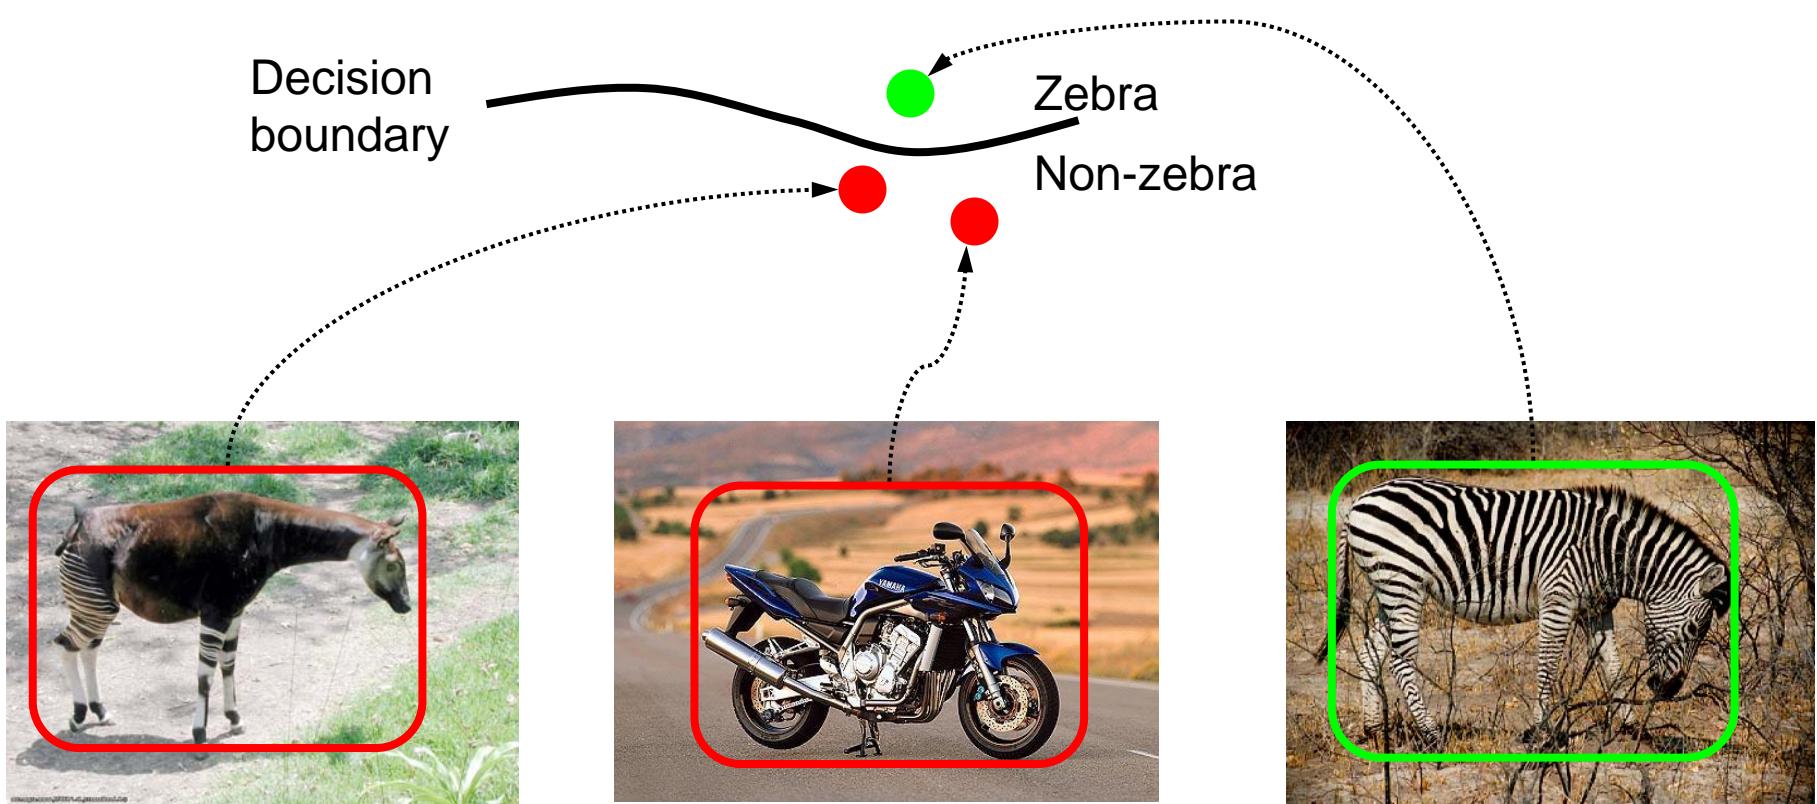

$$\frac{p(\text{zebra} | \text{image})}{p(\text{no zebra} | \text{image})} = \underbrace{\frac{p(\text{image} | \text{zebra})}{p(\text{image} | \text{no zebra})}}_{\text{likelihood ratio}} \cdot \underbrace{\frac{p(\text{zebra})}{p(\text{no zebra})}}_{\text{prior ratio}}$$

- **Discriminative methods model posterior**
- **Generative methods model likelihood and prior**

Discriminative

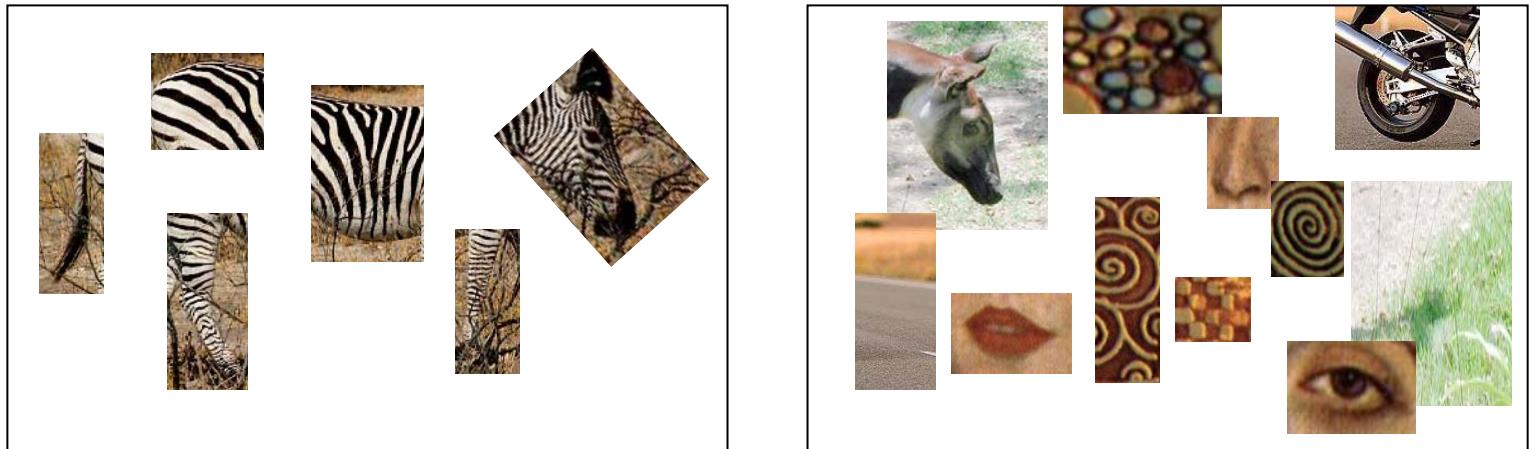

- Direct modeling of

$$\frac{p(\text{zebra} \mid \text{image})}{p(\text{no zebra} \mid \text{image})}$$

Generative

- Model $p(\text{image} | \text{zebra})$ and $p(\text{image} | \text{no zebra})$

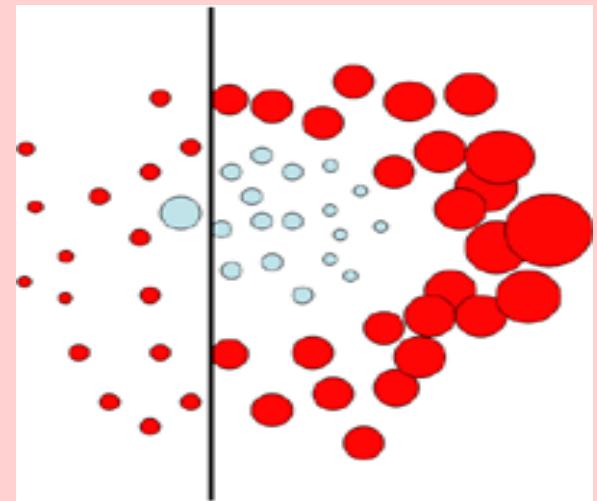

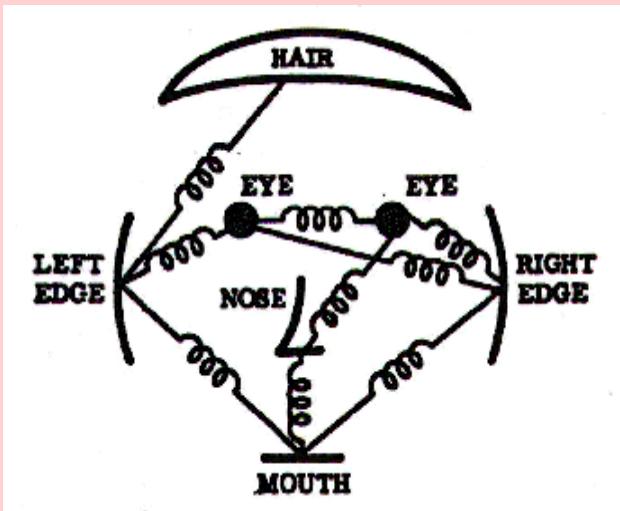

$p(\text{image} \text{zebra})$	$p(\text{image} \text{no zebra})$
 Low	Middle
 High	Middle → Low

Three main issues

- Representation
 - How to represent an object category
- Learning
 - How to form the classifier, given training data
- Recognition
 - How the classifier is to be used on novel data

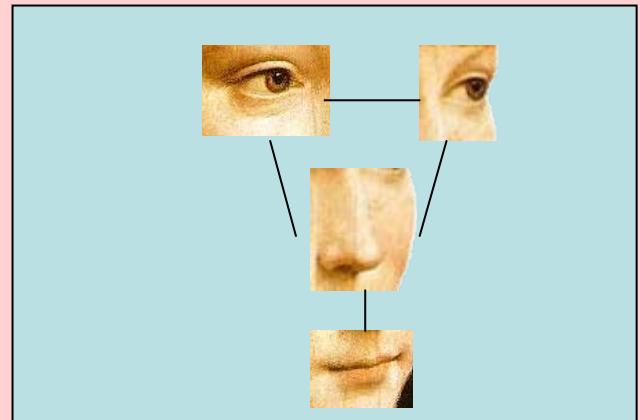

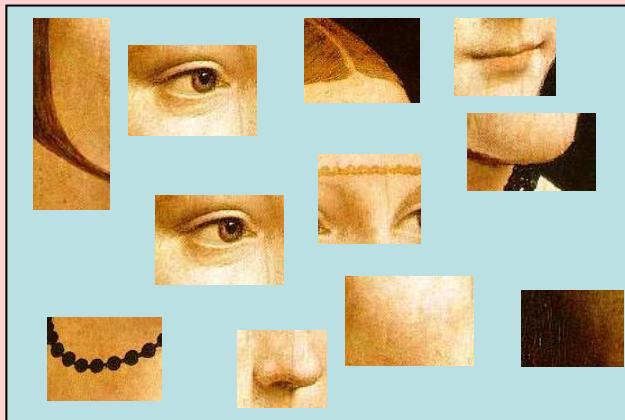

Representation

- Generative /
discriminative / hybrid

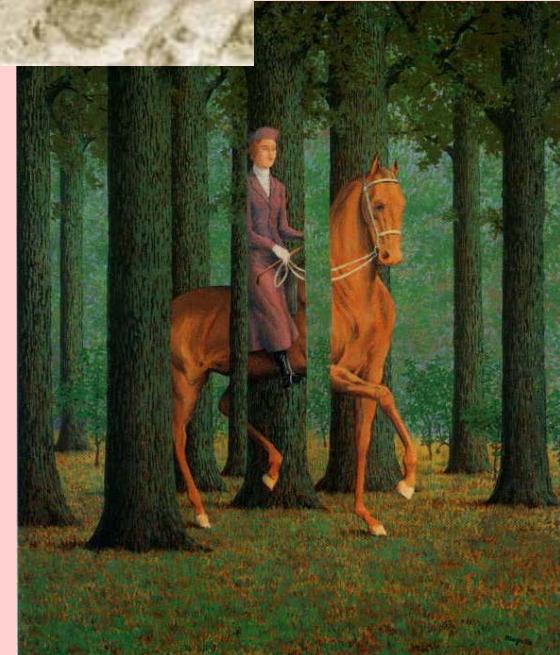

Representation

- Generative / discriminative / hybrid
- Appearance only or location and appearance

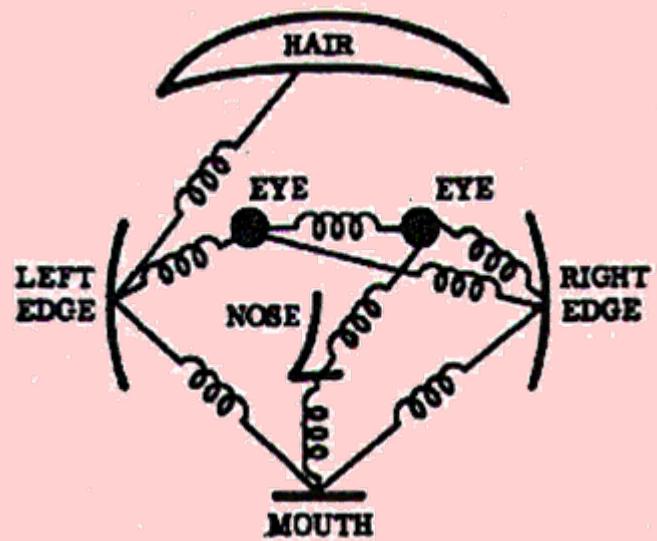

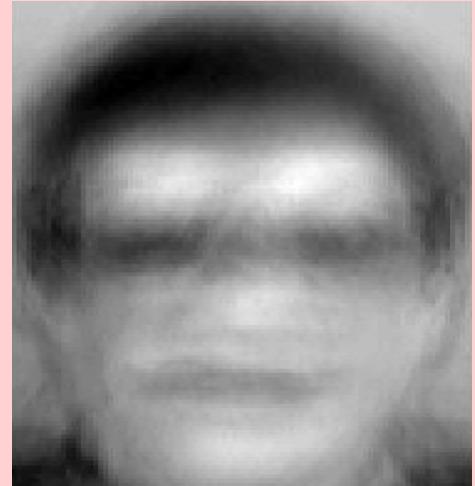

Representation

- Generative / discriminative / hybrid
- Appearance only or location and appearance
- Invariances
 - View point
 - Illumination
 - Occlusion
 - Scale
 - Deformation
 - Clutter
 - etc.

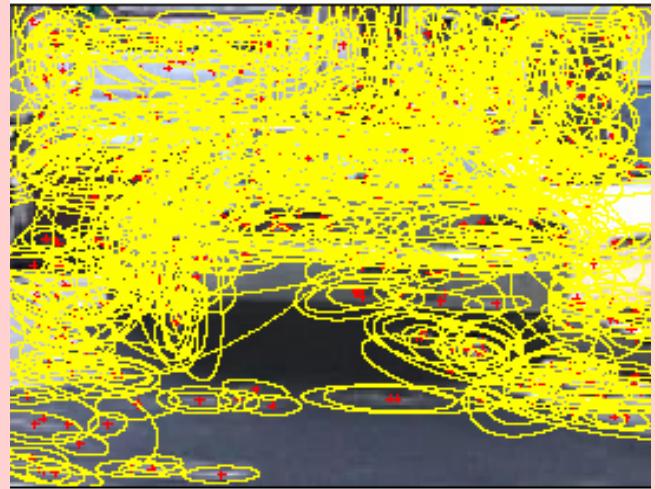

Representation

- Generative / discriminative / hybrid
- Appearance only or location and appearance
- invariances
- Part-based or global w/sub-window

Representation

- Generative / discriminative / hybrid
- Appearance only or location and appearance
- invariances
- Parts or global w/sub-window
- Use set of features or each pixel in image

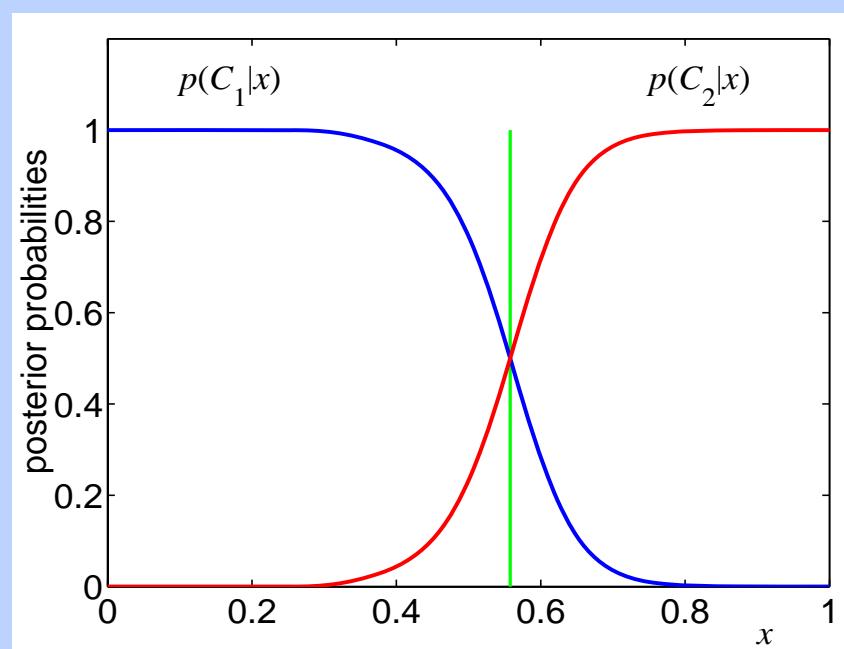

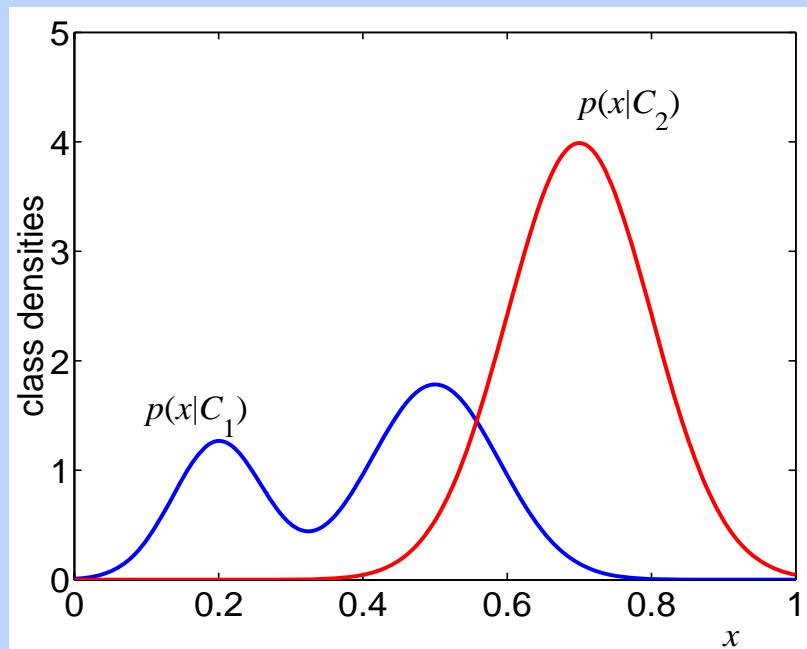

Learning

- Unclear how to model categories, so we learn what distinguishes them rather than manually specify the difference -- hence current interest in machine learning

Learning

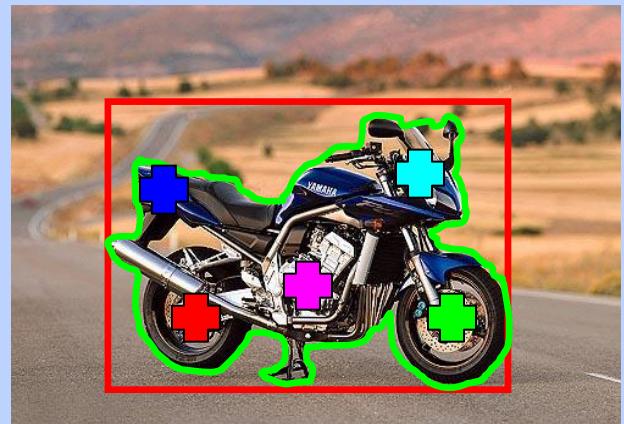

- Unclear how to model categories, so we learn what distinguishes them rather than manually specify the difference -- hence current interest in machine learning)
- Methods of training: generative vs. discriminative

Learning

- Unclear how to model categories, so we learn what distinguishes them rather than manually specify the difference -- hence current interest in machine learning)
- What are you maximizing? Likelihood (Gen.) or performances on train/validation set (Disc.)
- Level of supervision
 - Manual segmentation; bounding box; image labels; noisy labels

Bag-of-words models

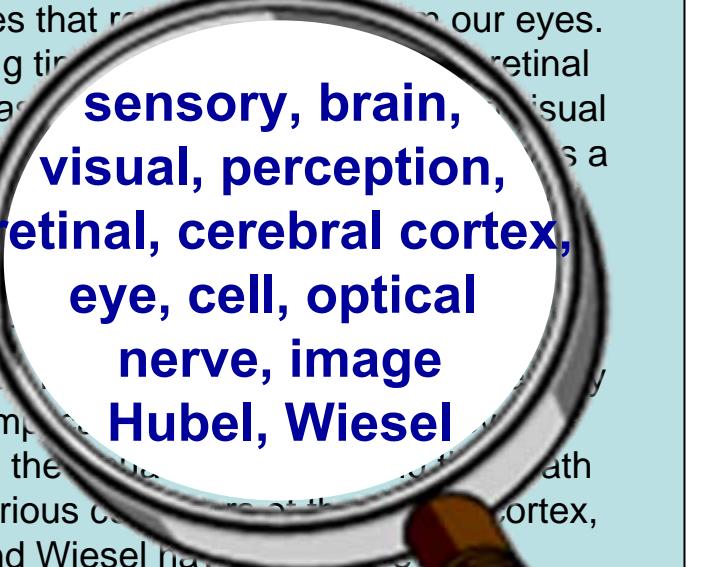

Object

Bag of ‘words’

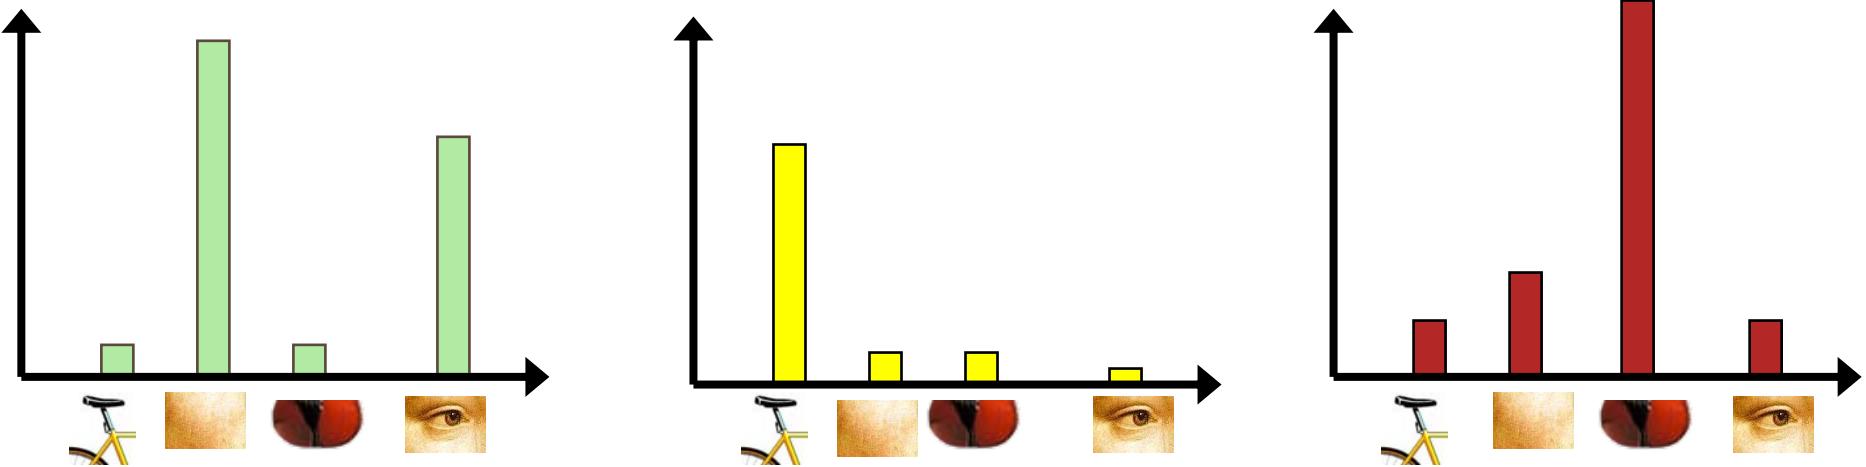

Analogy to documents

Of all the sensory impressions proceeding to the brain, the visual experiences are the dominant ones. Our perception of the world around us is based essentially on the messages that reach us through our eyes. For a long time it was believed that the retinal image was processed by the visual centers in the brain. In 1960, as a movie screen, Hubel and Wiesel discovered that the visual image is processed by the eye, cell, optical nerve, image falling on the retina undergoes top-down analysis in a system of nerve cells stored in columns. In this system each column has its specific function and is responsible for a specific detail in the pattern of the retinal image.

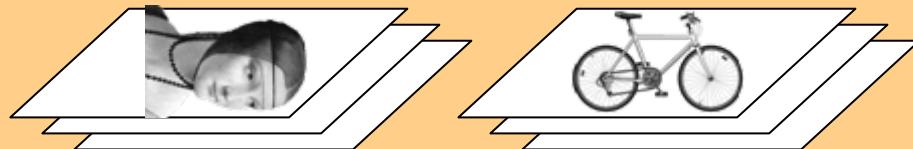

China is forecasting a trade surplus of \$90bn (£51bn) to \$100bn this year, a threefold increase on 2004's \$32bn. The Commerce Ministry said the surplus would be created by a predicted 30% increase in exports to \$750bn, compared with \$660bn. This could annoy the US, which China's commerce minister, Chen Deming, deliberately agrees. The Chinese yuan is governed by the central bank, which also needs to meet the demand so that the country can import more. The yuan against the dollar has appreciated and permitted it to trade within a narrow band, but the US wants the yuan to be allowed to trade freely. However, Beijing has made it clear that it will take its time and tread carefully before allowing the yuan to rise further in value.

Learning and Recognition

2 case studies

1. Naïve Bayes classifier

- Csurka et al. 2004

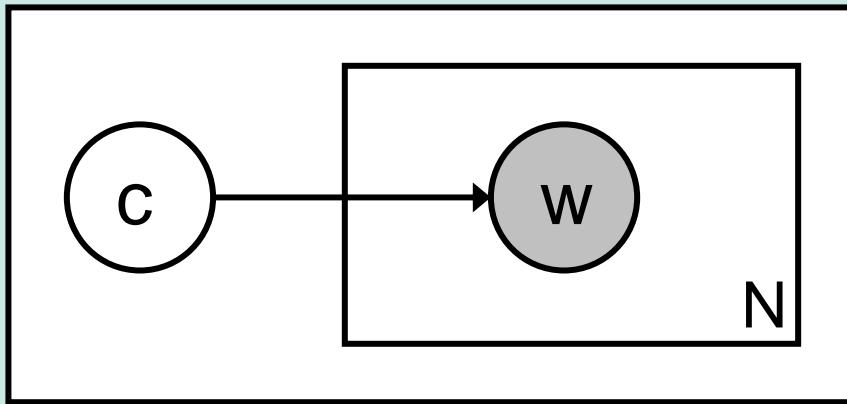

2. Hierarchical Bayesian text models (pLSA and LDA)

- Background: Hoffman 2001, Blei et al. 2004
- Object categorization: Sivic et al. 2005, Sudderth et al. 2005
- Natural scene categorization: Fei-Fei et al. 2005

First, some notations

- w_n : each patch in an image
 - $w_n = [0, 0, \dots, 1, \dots, 0, 0]^T$
- w : a collection of all N patches in an image
 - $w = [w_1, w_2, \dots, w_N]$
- d_j : the j^{th} image in an image collection
- c : category of the image
- z : theme or topic of the patch

Case #1: the Naïve Bayes model

$$c^* = \arg \max_c p(c | w) \propto p(c)p(w|c) = p(c) \prod_{n=1}^N p(w_n | c)$$

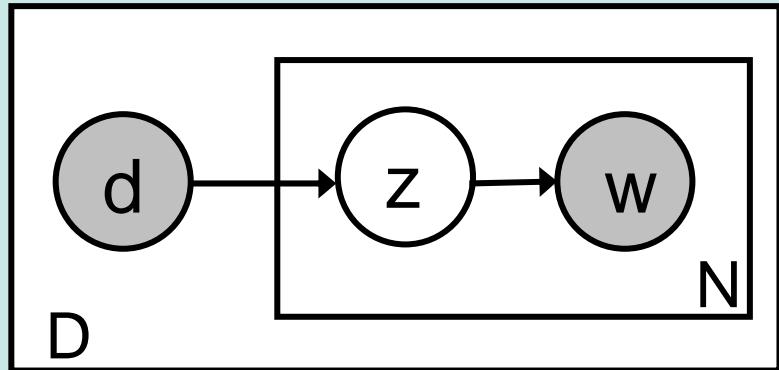

Object class

Probabilistic Latent Semantic Analysis (pLSA)

“face”

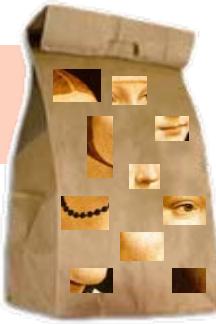

Case #2: Hierarchical Bayesian text models

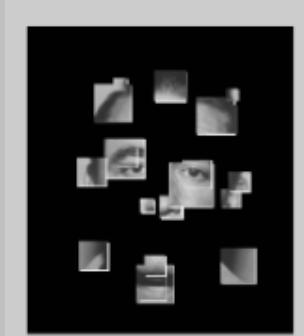

Another application

- Human action classification

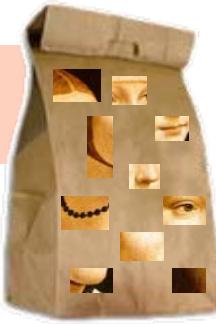

Invariance issues

- Scale and rotation
 - Implicit
 - Detectors and descriptors

Invariance issues

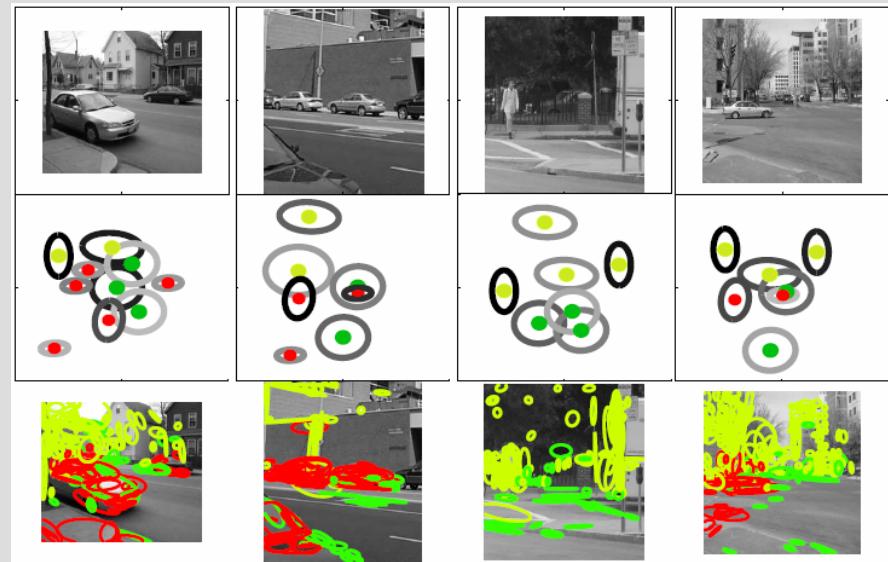

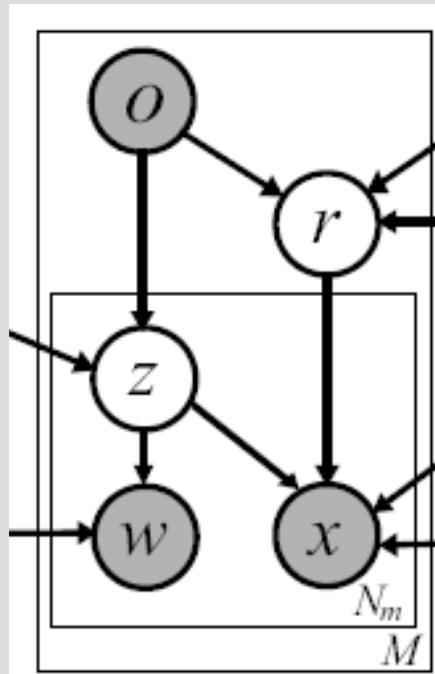

- Scale and rotation
- Occlusion
 - Implicit in the models
 - Codeword distribution: small variations
 - (In theory) Theme (z) distribution: different occlusion patterns

Invariance issues

- Scale and rotation
- Occlusion
- Translation
 - Encode (relative) location information

Invariance issues

- Scale and rotation
- Occlusion
- Translation
- View point (in theory)
 - Codewords: detector and descriptor
 - Theme distributions: different view points

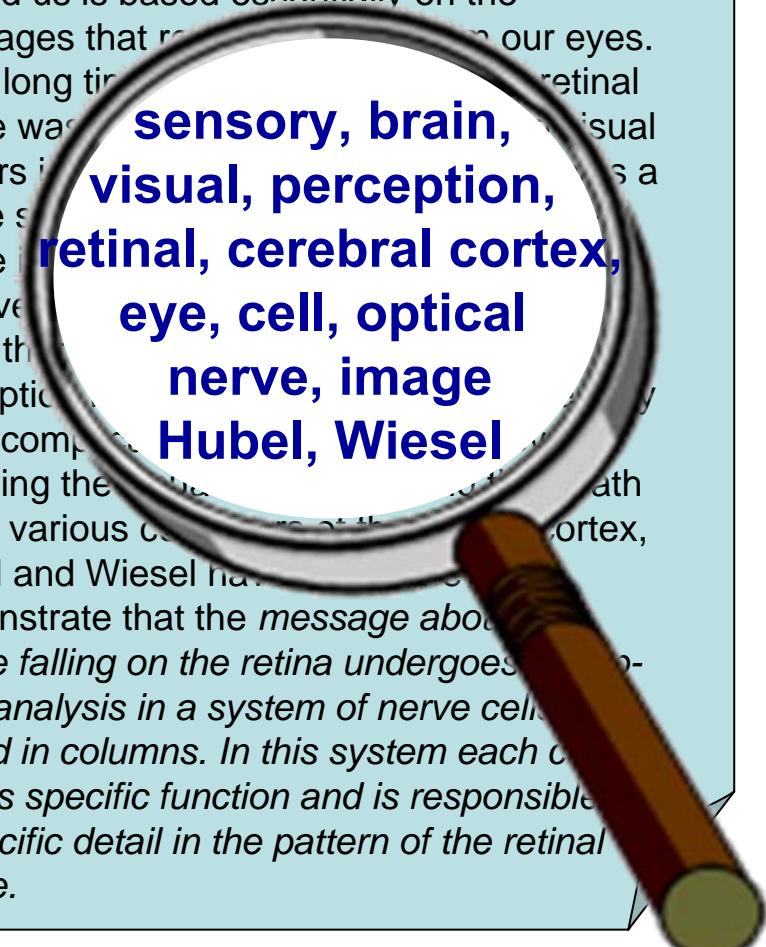

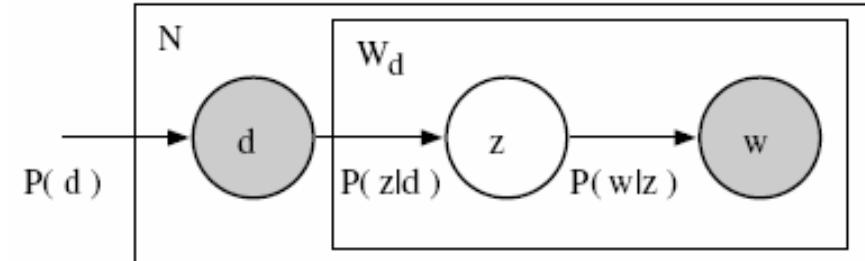

Model properties

- Intuitive
 - Analogy to documents

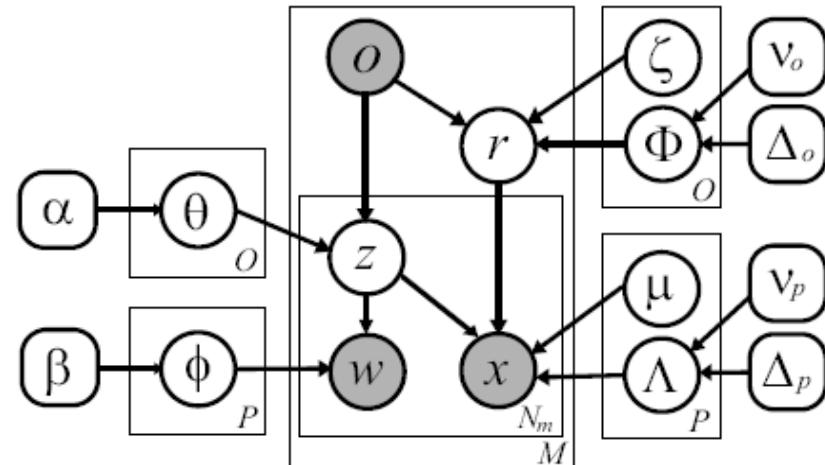

Of all the sensory impressions proceeding to the brain, the visual experiences are the dominant ones. Our perception of the world around us is based essentially on the messages that reach our brain from our eyes. For a long time it was believed that the retinal image was processed directly in the visual centers in the brain, much like watching a movie screen. In 1960, two scientists discovered that the visual system is much more complex than previously thought. Following the work of the two scientists, Hubel and Wiesel have demonstrated that the message about the image falling on the retina undergoes a top-down analysis in a system of nerve cells stored in columns. In this system each column has its specific function and is responsible for a specific detail in the pattern of the retinal image.

Model properties

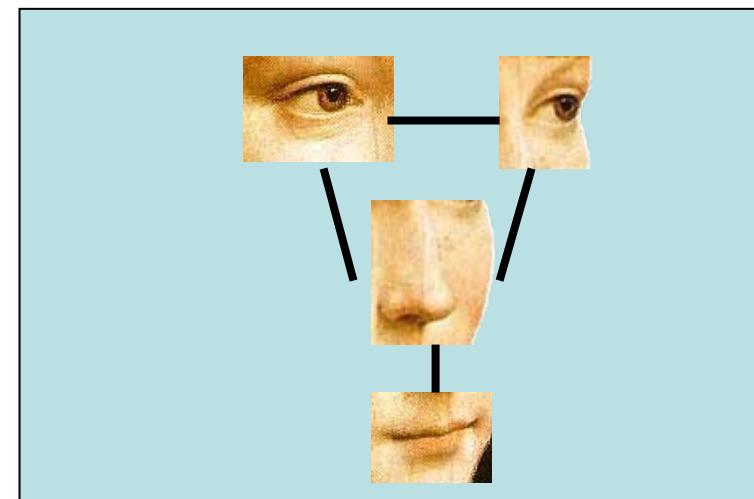

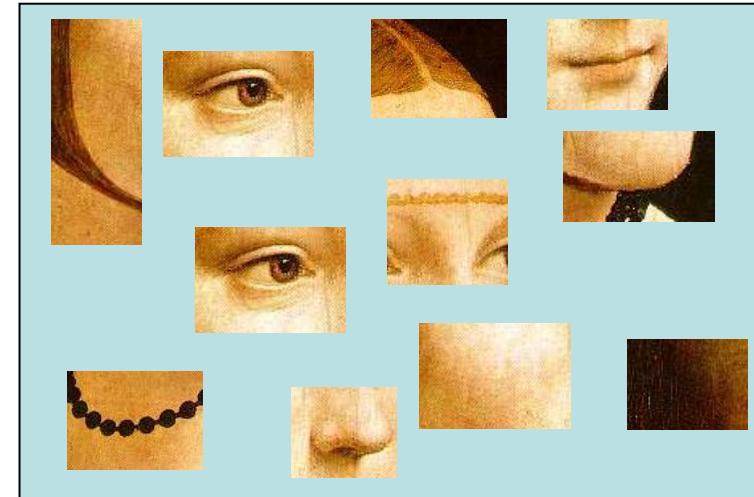

- Intuitive
- (Could use)
generative models
 - Convenient for weakly- or un-supervised training
 - Prior information
 - Hierarchical Bayesian framework

Model properties

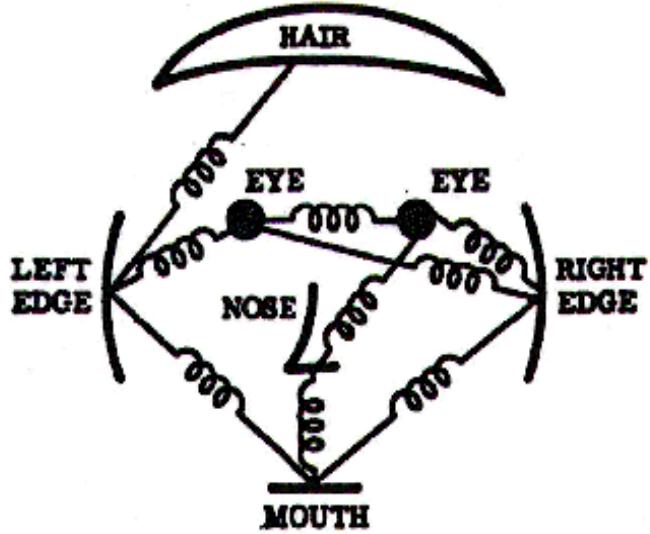

- Intuitive
- (Could use) generative models
- Learning and recognition relatively fast
 - Compare to other methods

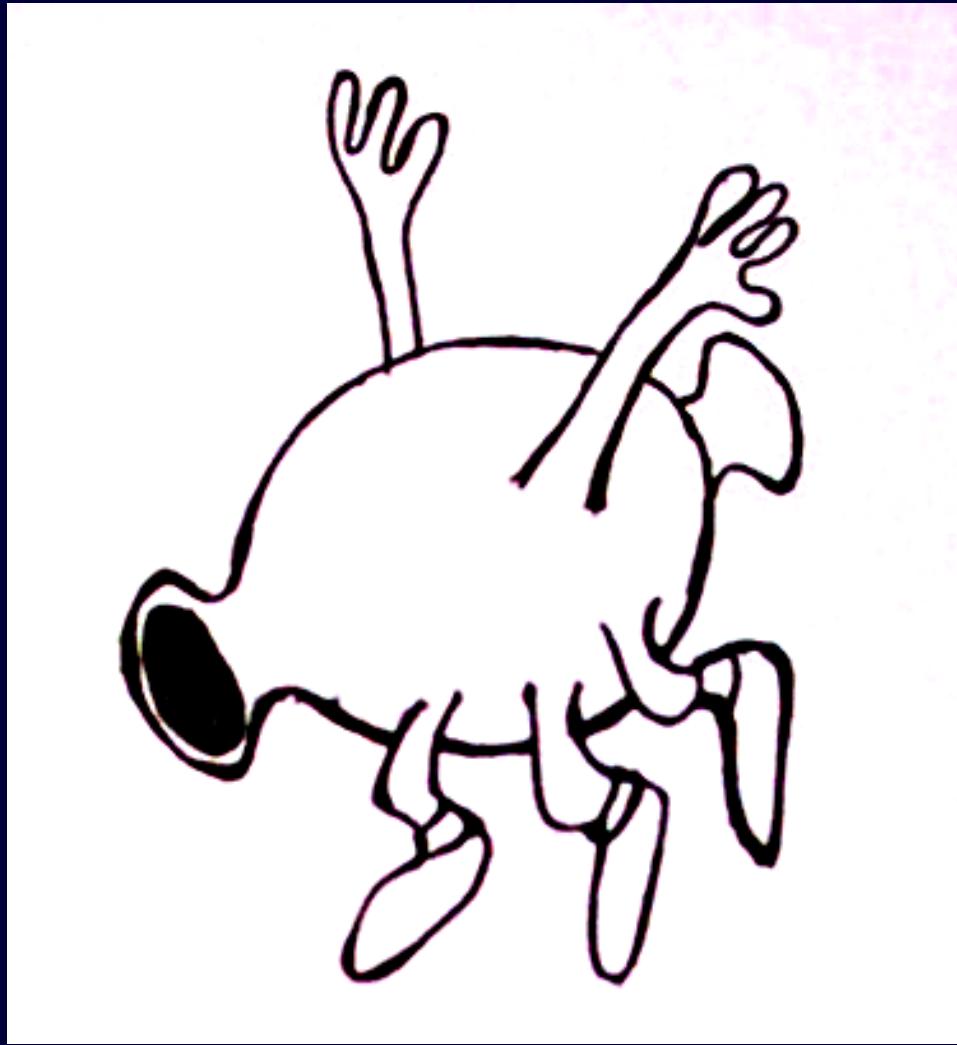

Weakness of the model

- No rigorous geometric information of the object components
- It's intuitive to most of us that objects are made of parts – no such information
- Not extensively tested yet for
 - View point invariance
 - Scale invariance
- Segmentation and localization unclear

Part 3: discriminative methods

Discriminative methods

Object detection and recognition is formulated as a classification problem.

The image is partitioned into a set of overlapping windows

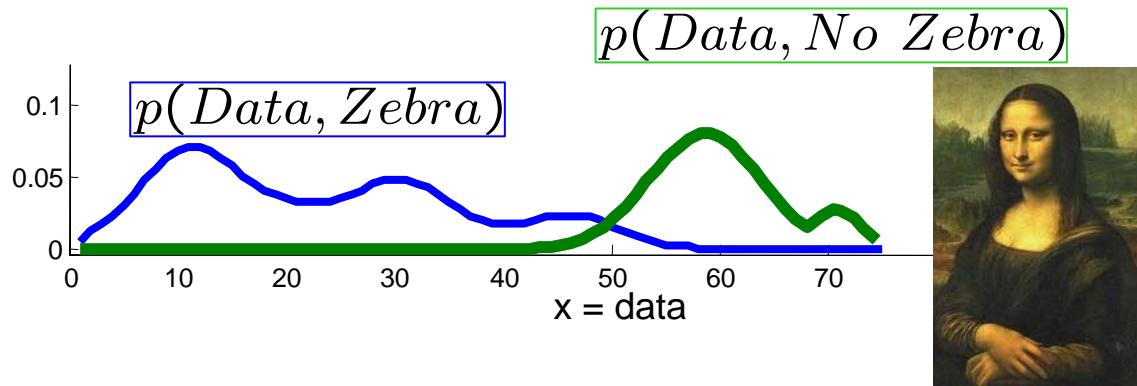

... and a decision is taken at each window about if it contains a target object or not.

Discriminative vs. generative

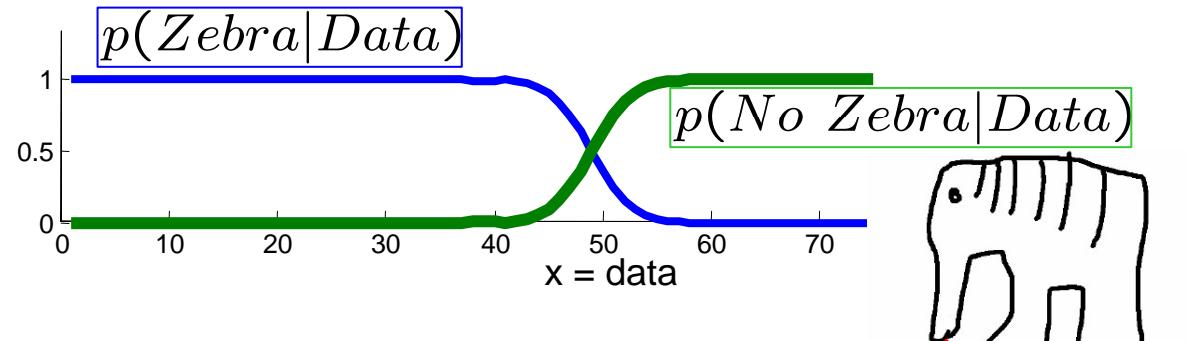

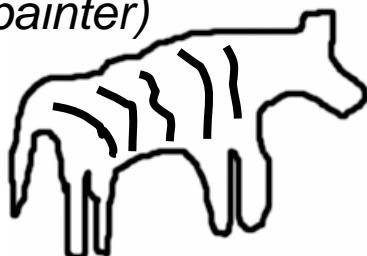

- Generative model

(The artist)

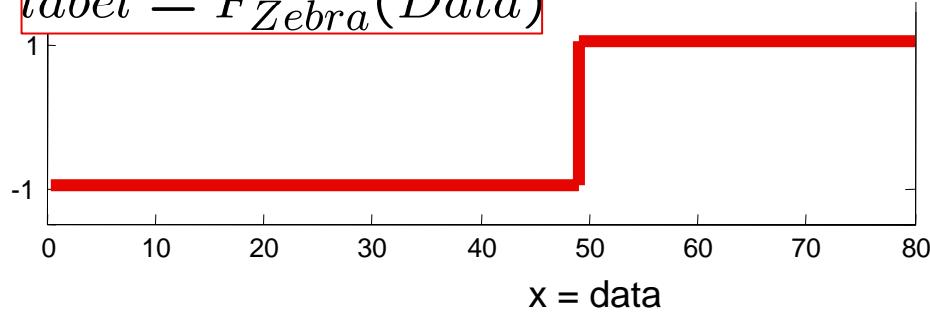

- Discriminative model

(The lousy painter)

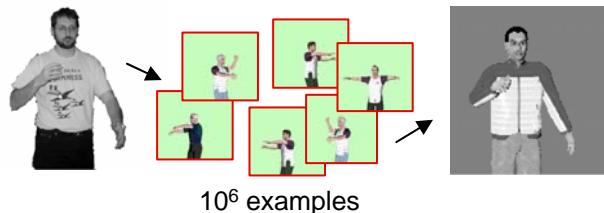

- Classification function

$$\text{label} = F_{\text{Zebra}}(\text{Data})$$

Discriminative methods

Formulation

- Formulation: binary classification

- Classification function

$$\hat{y} = F(x) \quad \text{Where } F(x) \text{ belongs to some family of functions}$$

- Minimize misclassification error

(Not that simple: we need some guarantees that there will be generalization)

Overview of section

- Object detection with classifiers
- **Boosting**
 - Gentle boosting
 - Weak detectors
 - Object model
 - Object detection
- Multiclass object detection

Why boosting?

- A simple algorithm for learning robust classifiers
 - Freund & Shapire, 1995
 - Friedman, Hastie, Tibshhirani, 1998
- Provides efficient algorithm for sparse visual feature selection
 - *Tieu & Viola, 2000*
 - *Viola & Jones, 2003*
- Easy to implement, not requires external optimization tools.

Boosting

- Defines a classifier using an additive model:

$$F(x) = \alpha_1 f_1(x) + \alpha_2 f_2(x) + \alpha_3 f_3(x) + \dots$$

The diagram illustrates the structure of a strong classifier $F(x)$ as an additive model. It shows the equation $F(x) = \alpha_1 f_1(x) + \alpha_2 f_2(x) + \alpha_3 f_3(x) + \dots$. To the left of the equation, there are two vertical arrows pointing upwards from the text "Features vector" at the bottom to the terms $f_1(x)$ and $f_2(x)$ respectively. To the right of the equation, there are two vertical arrows pointing upwards from the text "Weight" at the bottom to the coefficients α_1 and α_2 respectively. The text "Strong classifier" is positioned to the left of the first arrow, and "Weak classifier" is positioned to the right of the second arrow.

Strong classifier

Weak classifier

Weight

Features vector

Boosting

- Defines a classifier using an additive model:

$$F(x) = \alpha_1 f_1(x) + \alpha_2 f_2(x) + \alpha_3 f_3(x) + \dots$$

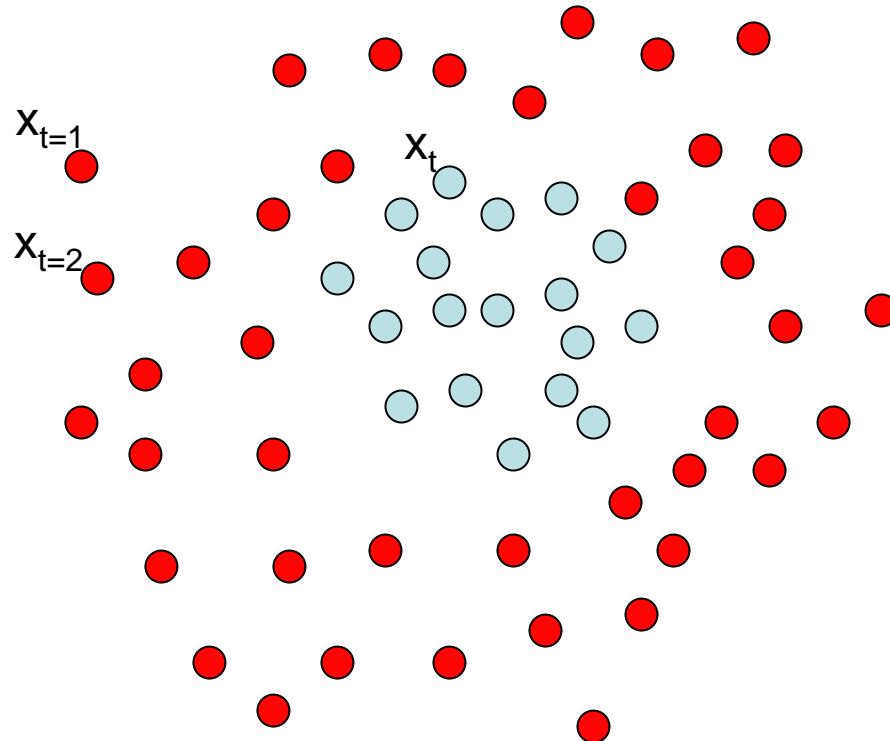

The diagram illustrates the additive model of a strong classifier. It shows the equation $F(x) = \alpha_1 f_1(x) + \alpha_2 f_2(x) + \alpha_3 f_3(x) + \dots$. To the left of the equation, there are two vertical arrows pointing upwards from the text 'Features vector' to the terms $f_1(x)$ and $f_2(x)$. To the right of the equation, there are two vertical arrows pointing upwards from the text 'Weight' to the coefficients α_1 and α_2 . The text 'Strong classifier' is positioned to the left of the first term $\alpha_1 f_1(x)$, and the text 'Weak classifier' is positioned to the right of the first term $\alpha_1 f_1(x)$.

- We need to define a family of weak classifiers

$f_k(x)$ from a family of weak classifiers

Boosting

- It is a sequential procedure:

Each data point has
a class label:

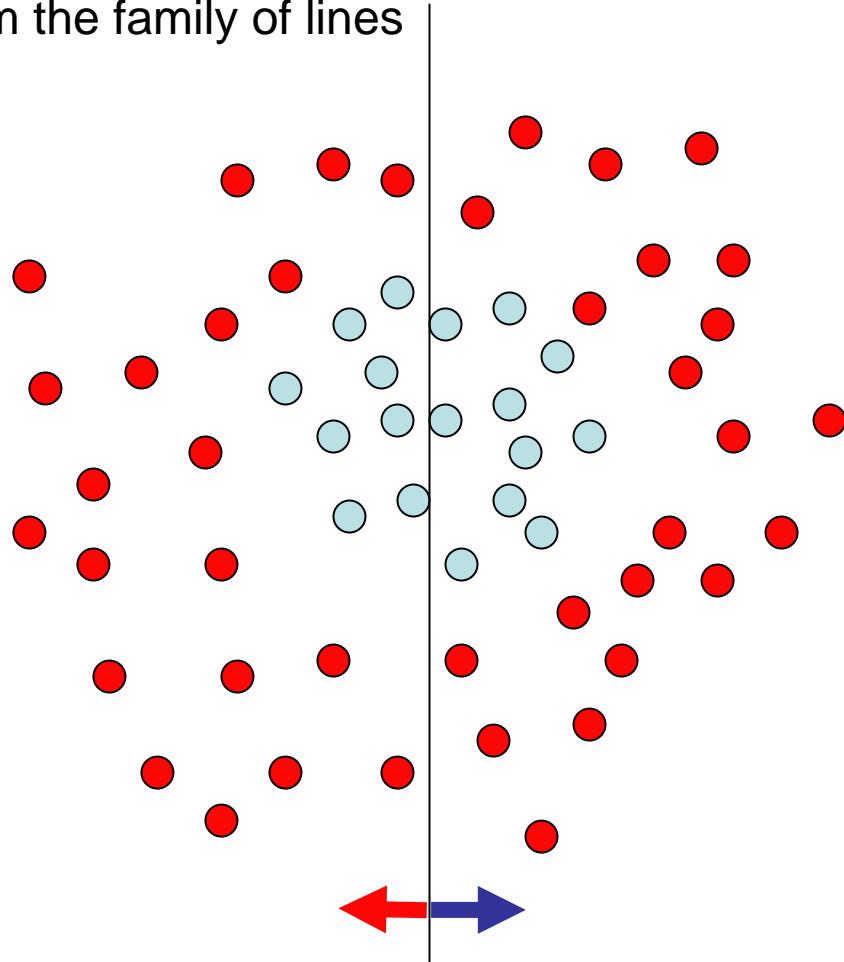

$$y_t = \begin{cases} +1 (\text{red}) \\ -1 (\text{light blue}) \end{cases}$$

and a weight:

$$w_t = 1$$

Toy example

Weak learners from the family of lines

Each data point has
a class label:

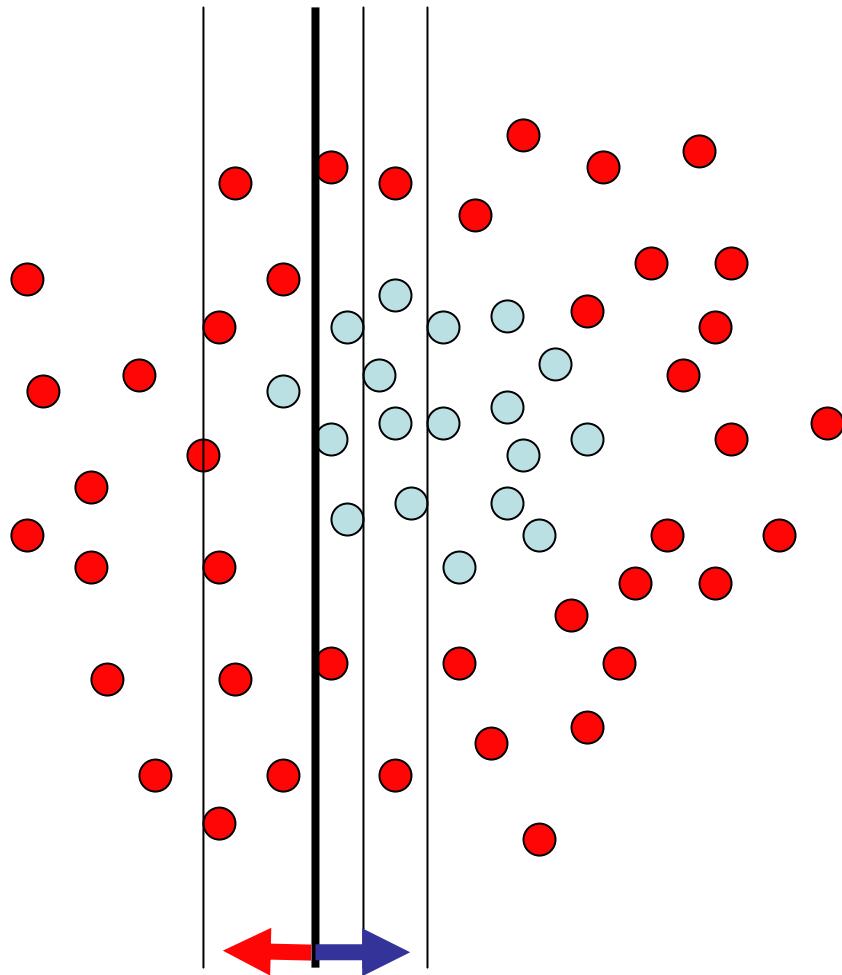

$$y_t = \begin{cases} +1 (\text{red circle}) \\ -1 (\text{light blue circle}) \end{cases}$$

and a weight:

$$w_t = 1$$

$h \Rightarrow p(\text{error}) = 0.5$ it is at chance

Toy example

Each data point has
a class label:

$$y_t = \begin{cases} +1 (\text{red circle}) \\ -1 (\text{light blue circle}) \end{cases}$$

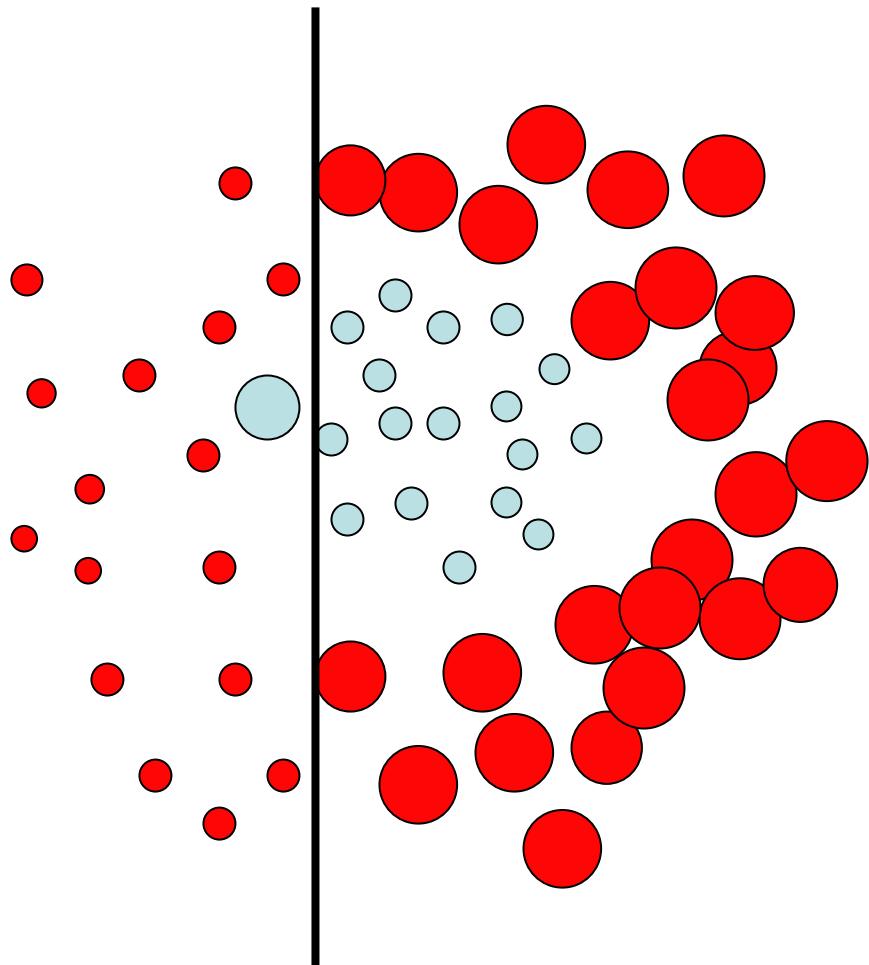

and a weight:

$$w_t = 1$$

This one seems to be the best

This is a ‘**weak classifier**’: It performs slightly better than chance.

Toy example

Each data point has
a class label:

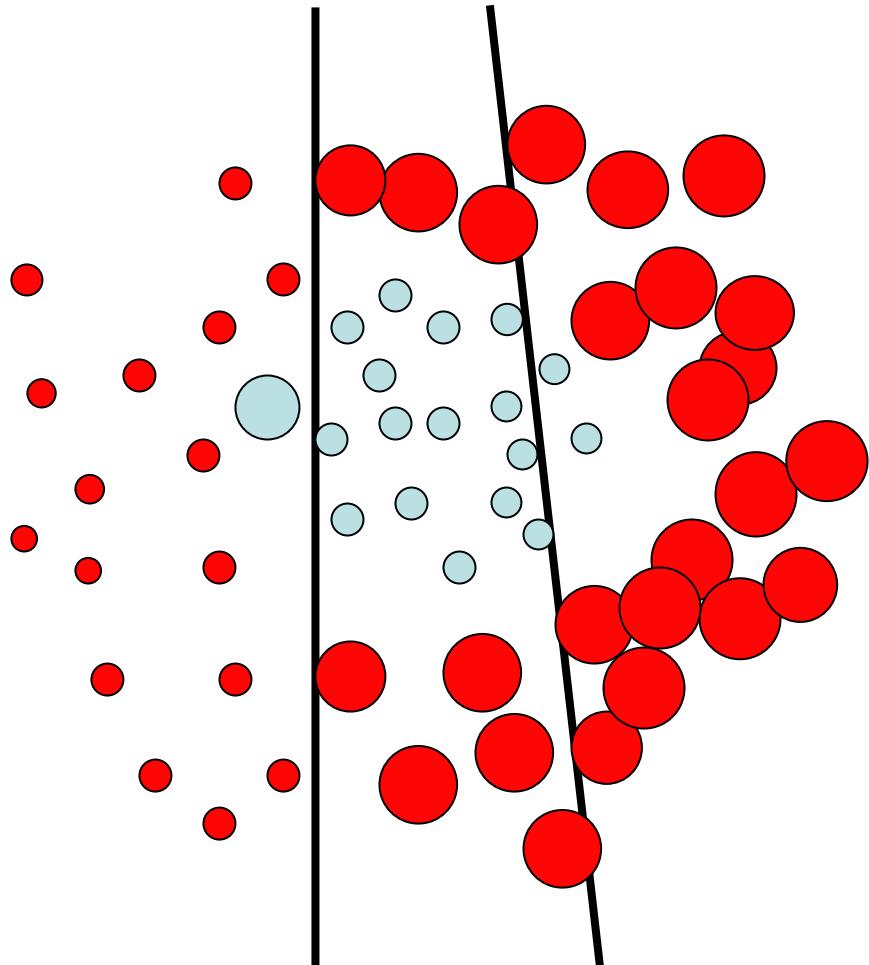

$$y_t = \begin{cases} +1 (\text{red}) \\ -1 (\text{light blue}) \end{cases}$$

We update the weights:

$$w_t \leftarrow w_t \exp\{-y_t H_t\}$$

We set a new problem for which the previous weak classifier performs at chance again

Toy example

Each data point has
a class label:

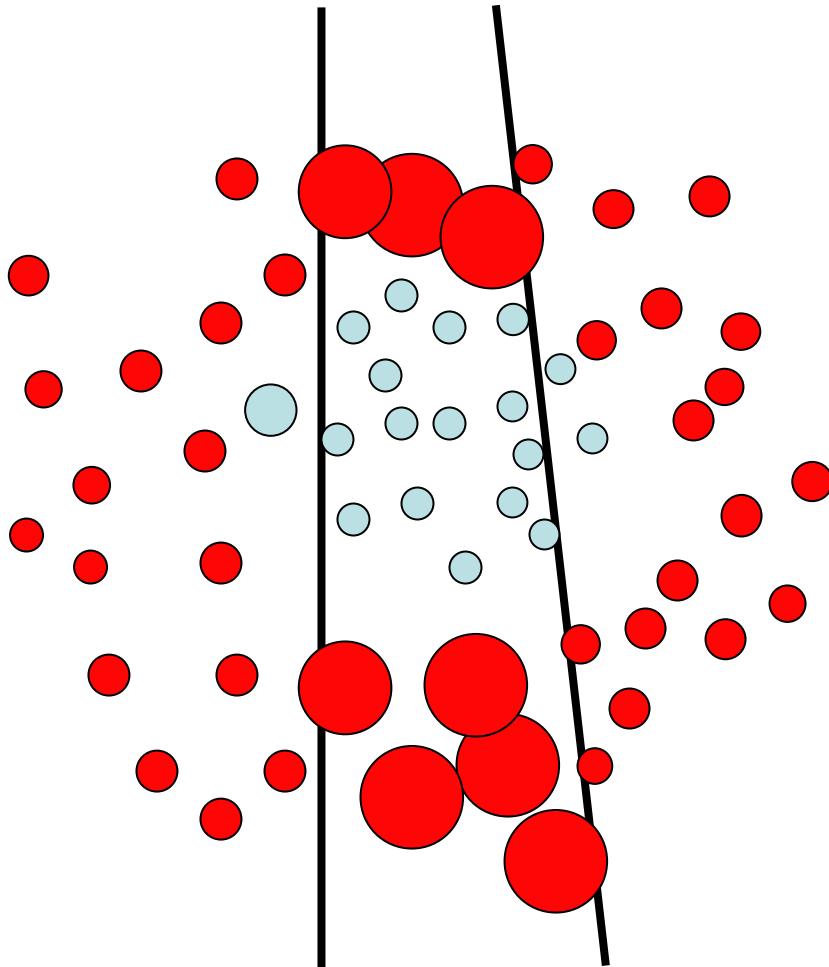

$$y_t = \begin{cases} +1 (\text{red}) \\ -1 (\text{light blue}) \end{cases}$$

We update the weights:

$$w_t \leftarrow w_t \exp\{-y_t H_t\}$$

We set a new problem for which the previous weak classifier performs at chance again

Toy example

Each data point has
a class label:

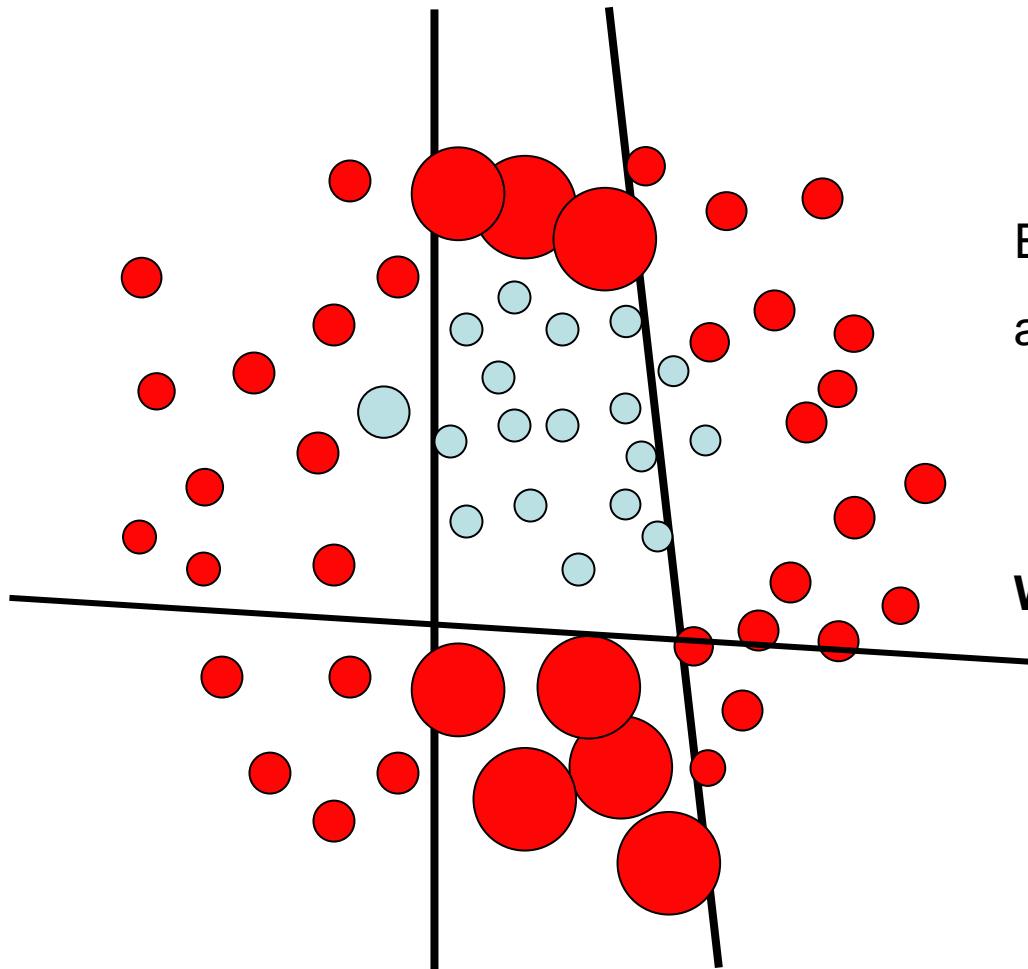

$$y_t = \begin{cases} +1 (\text{red circle}) \\ -1 (\text{light blue circle}) \end{cases}$$

We update the weights:

$$w_t \leftarrow w_t \exp\{-y_t H_t\}$$

We set a new problem for which the previous weak classifier performs at chance again

Toy example

Each data point has
a class label:

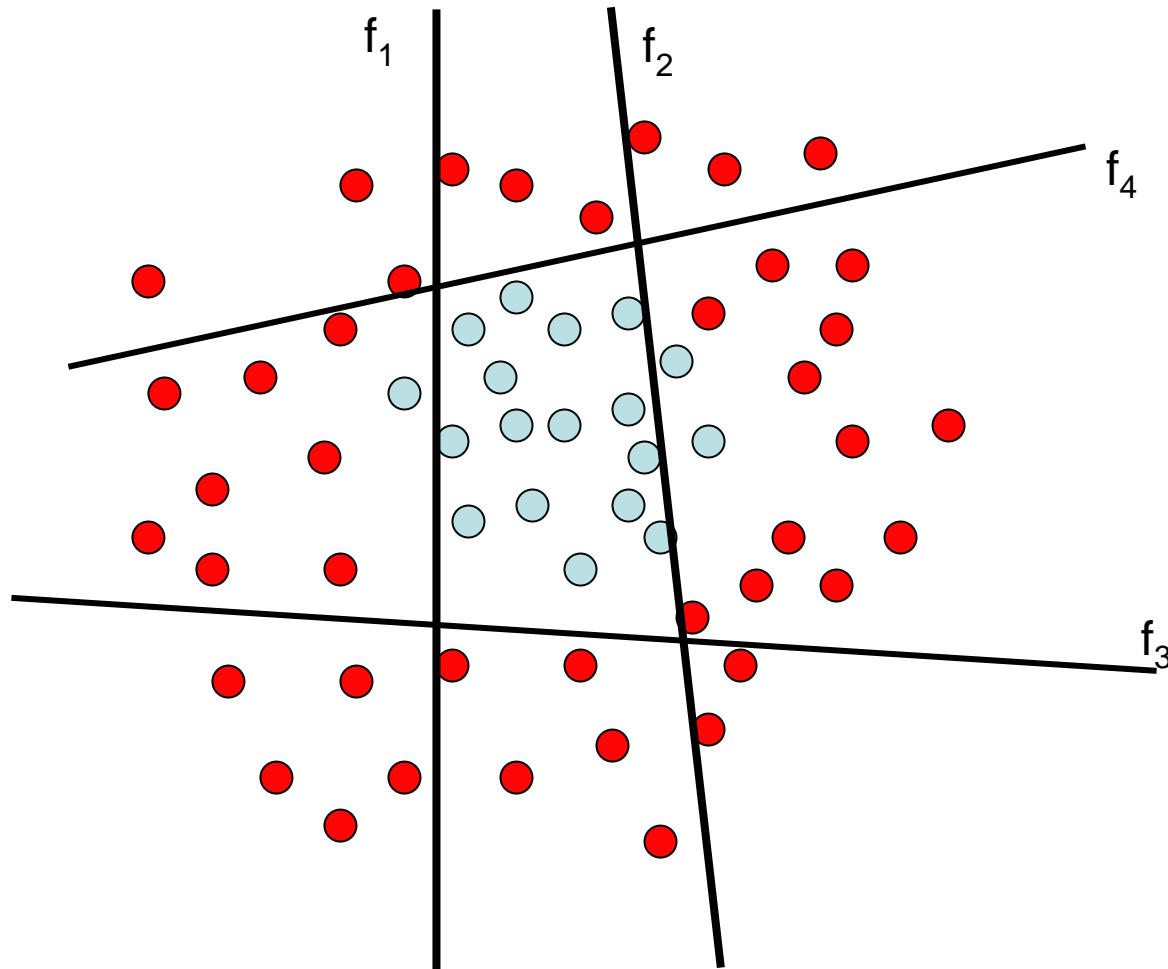

$$y_t = \begin{cases} +1 (\text{red}) \\ -1 (\text{light blue}) \end{cases}$$

We update the weights:

$$w_t \leftarrow w_t \exp\{-y_t H_t\}$$

We set a new problem for which the previous weak classifier performs at chance again

Toy example

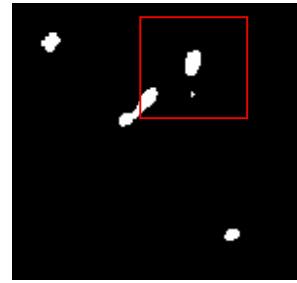

The strong (non- linear) classifier is built as the combination of all the weak (linear) classifiers.

From images to features: Weak detectors

We will now define a family of visual features that can be used as weak classifiers (“weak detectors”)

$$\longrightarrow h_i(I, x, y) \longrightarrow$$

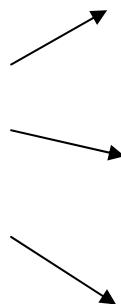

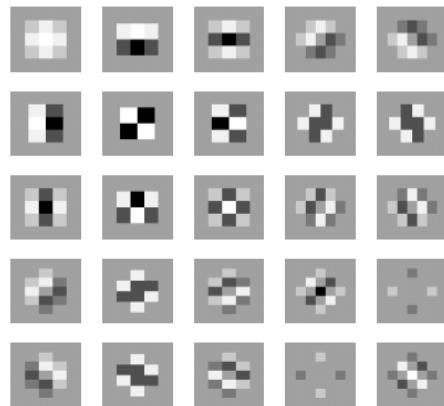

Takes image as input and the output is binary response.
The output is a weak detector.

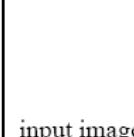

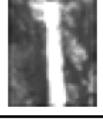

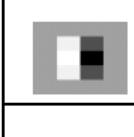

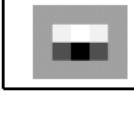

Weak detectors

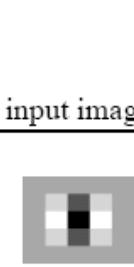

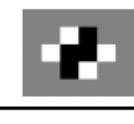

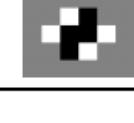

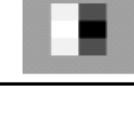

Textures of textures

Tieu and Viola, CVPR 2000

$$g_{i,j,k} = \sum_{pixels} ||I * f_i| \downarrow_2 * f_j| \downarrow_2 * f_k$$

input image		
		
		
		
		

input image		
		
		
		
		

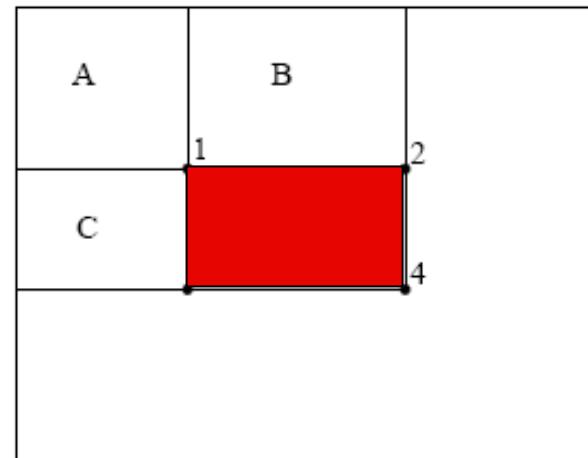

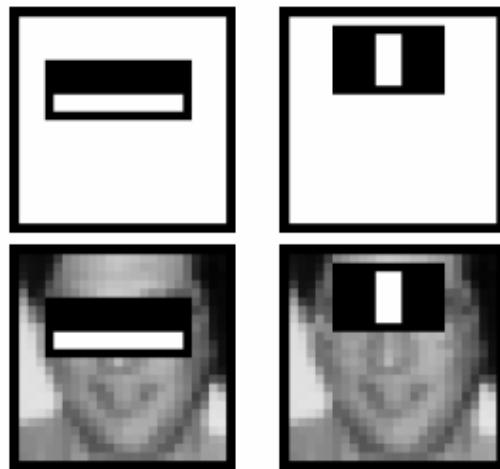

Every combination of three filters generates a different feature

This gives thousands of features. Boosting selects a sparse subset, so computations on test time are very efficient. Boosting also avoids overfitting to some extend.

Weak detectors

Haar filters and integral image

Viola and Jones, ICCV 2001

The average intensity in the block is computed with four sums independently of the block size.

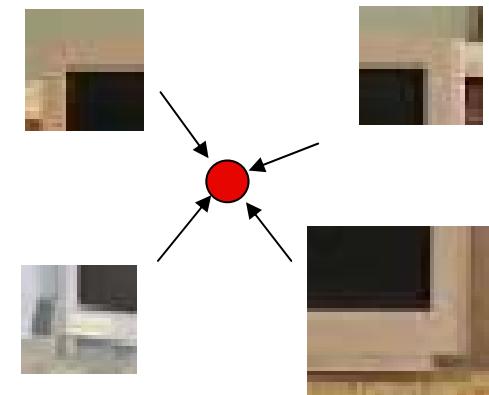

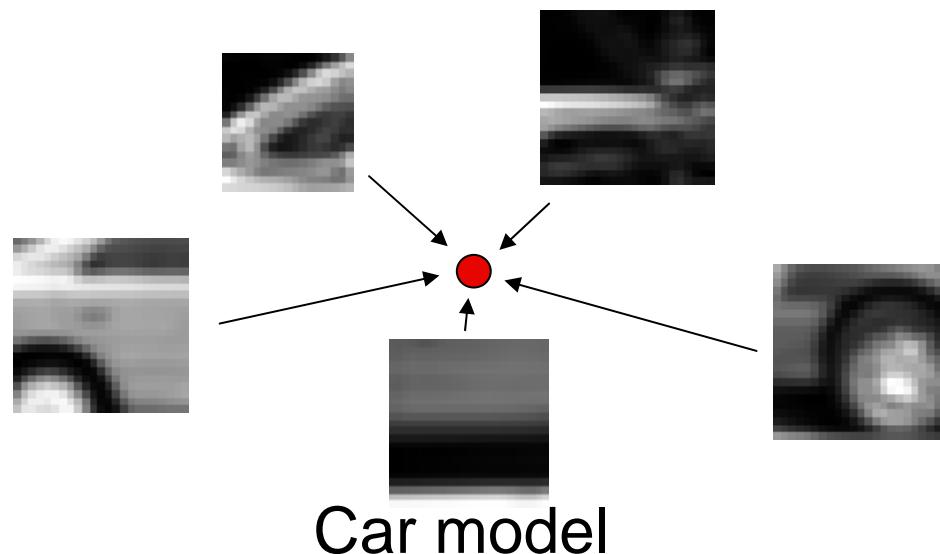

Weak detectors

Other weak detectors:

- Carmichael, Hebert 2004
- Yuille, Snow, Nitzberg, 1998
- Amit, Geman 1998
- Papageorgiou, Poggio, 2000
- Heisele, Serre, Poggio, 2001
- Agarwal, Awan, Roth, 2004
- Schneiderman, Kanade 2004
- ...

Weak detectors

Part based: similar to part-based generative models. We create weak detectors by using parts and voting for the object center location

Car model

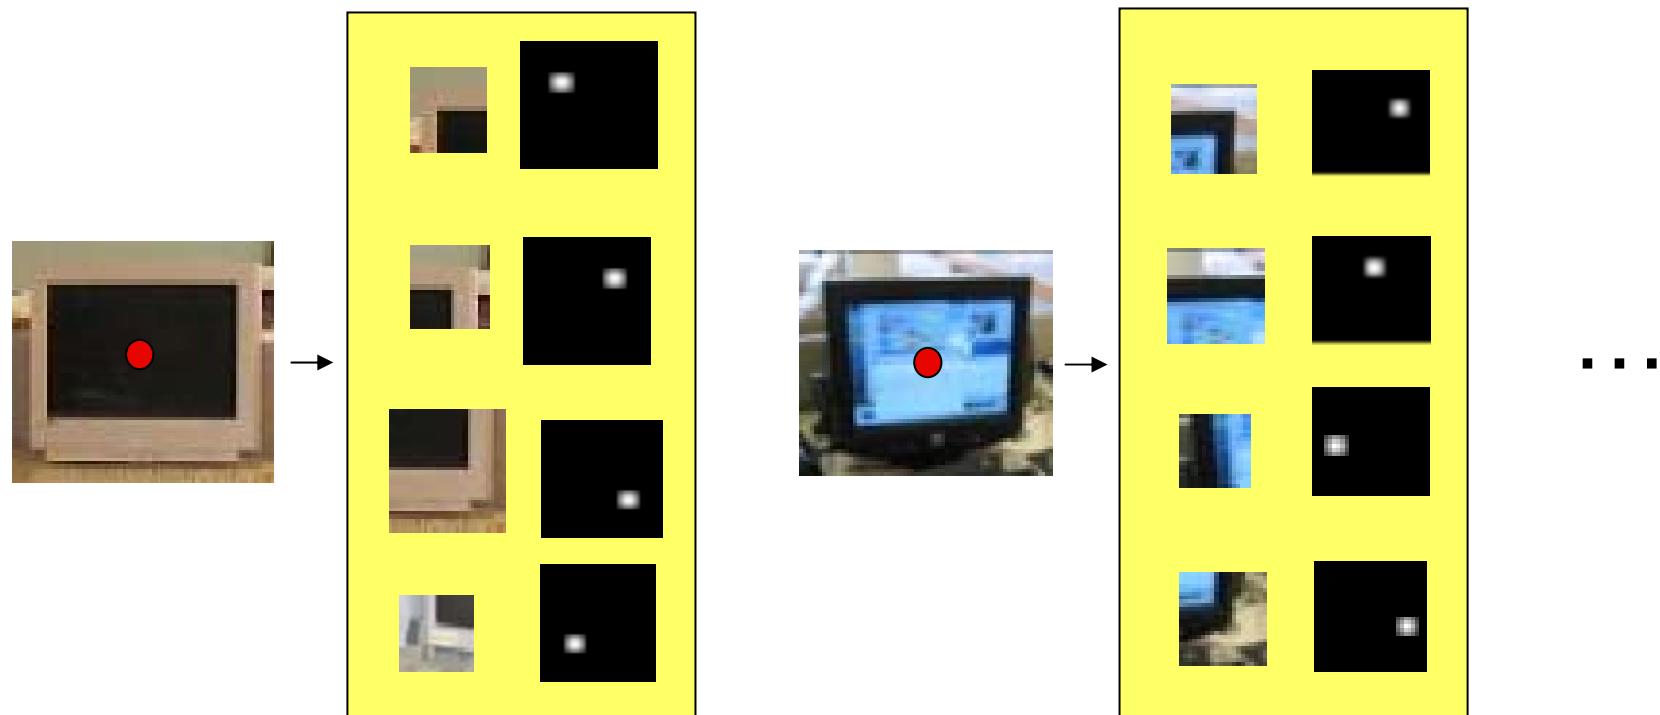

Screen model

These features are used for the detector on the course web site.

Weak detectors

First we collect a set of part templates from a set of training objects.

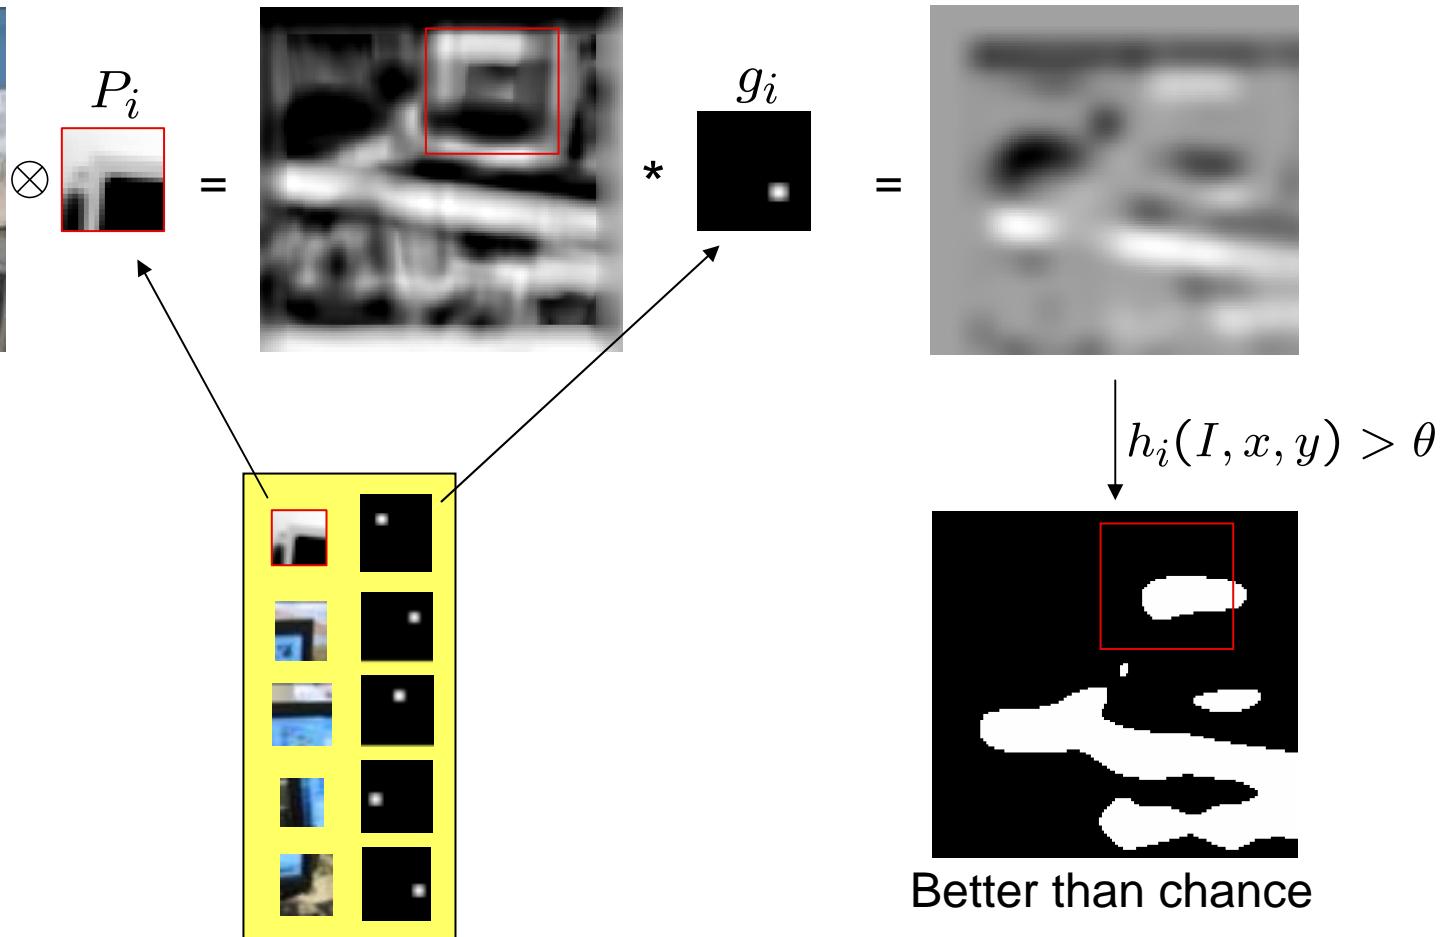

Vidal-Naquet, Ullman (2003)

Weak detectors

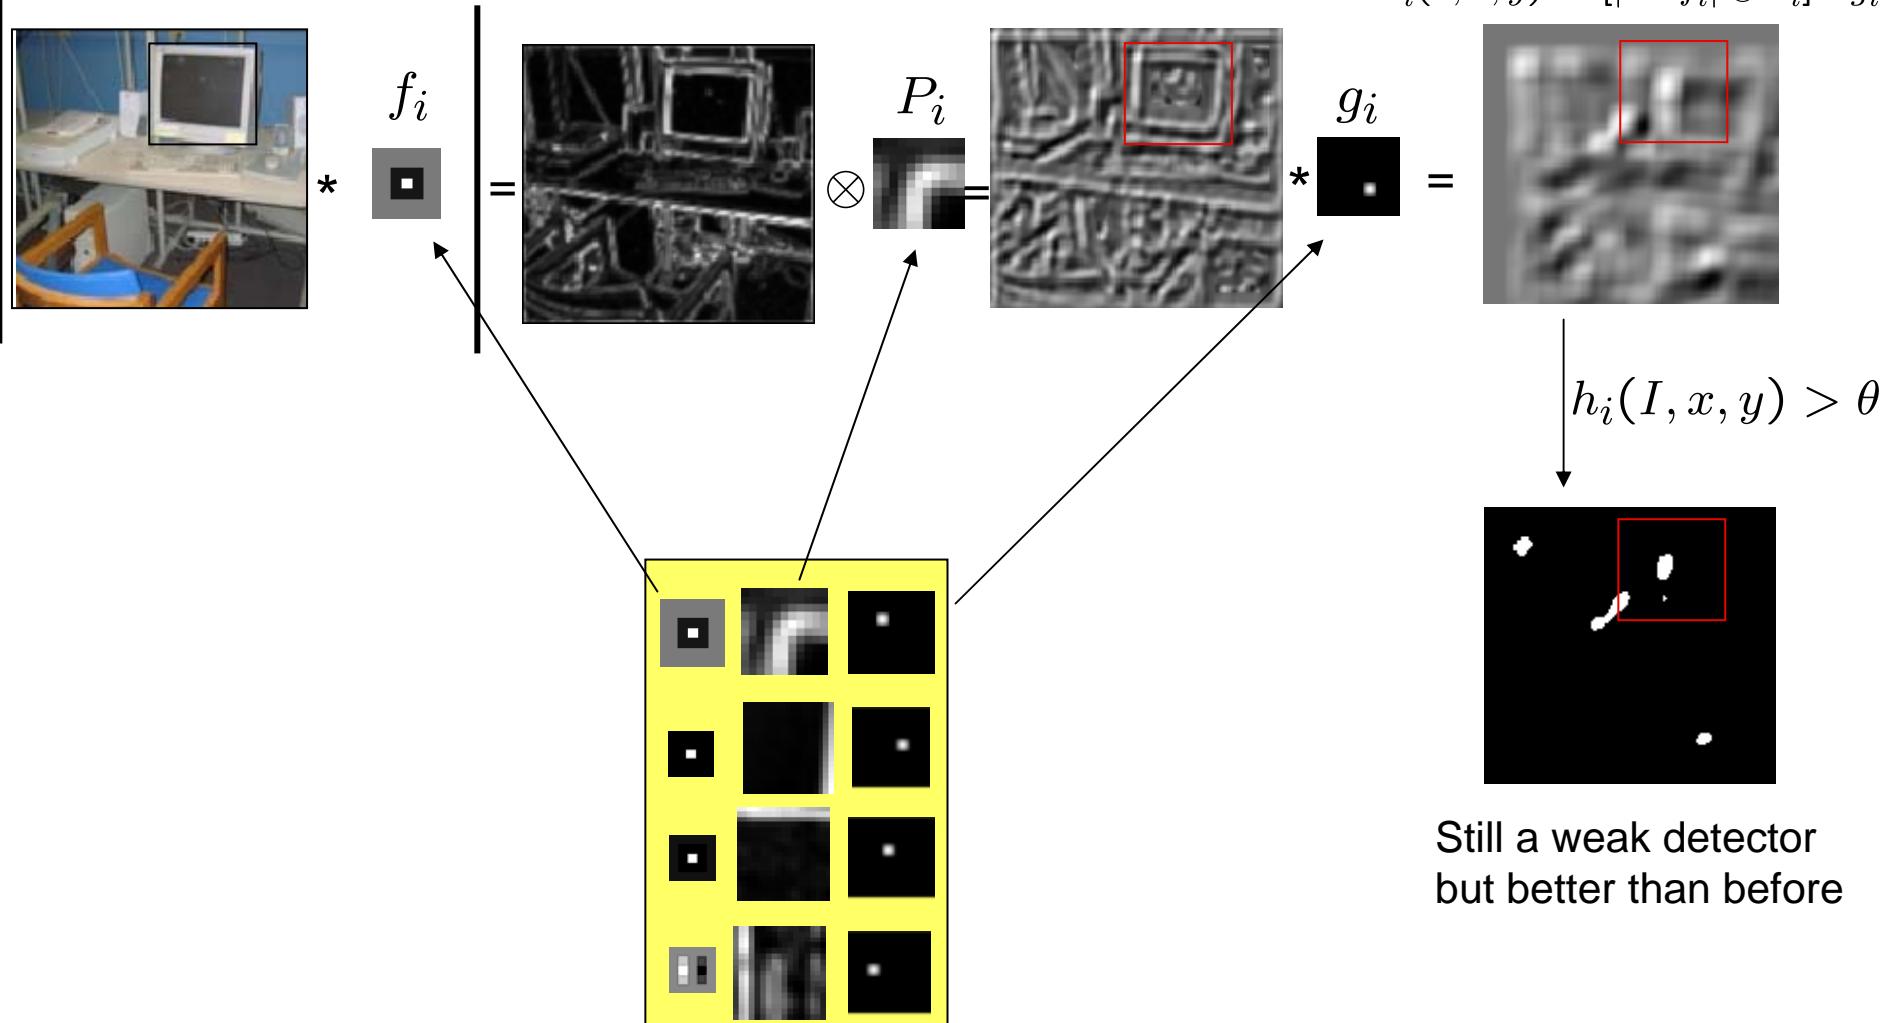

We now define a family of “weak detectors” as:

$$h_i(I, x, y) = [I \otimes P_i] * g_i$$

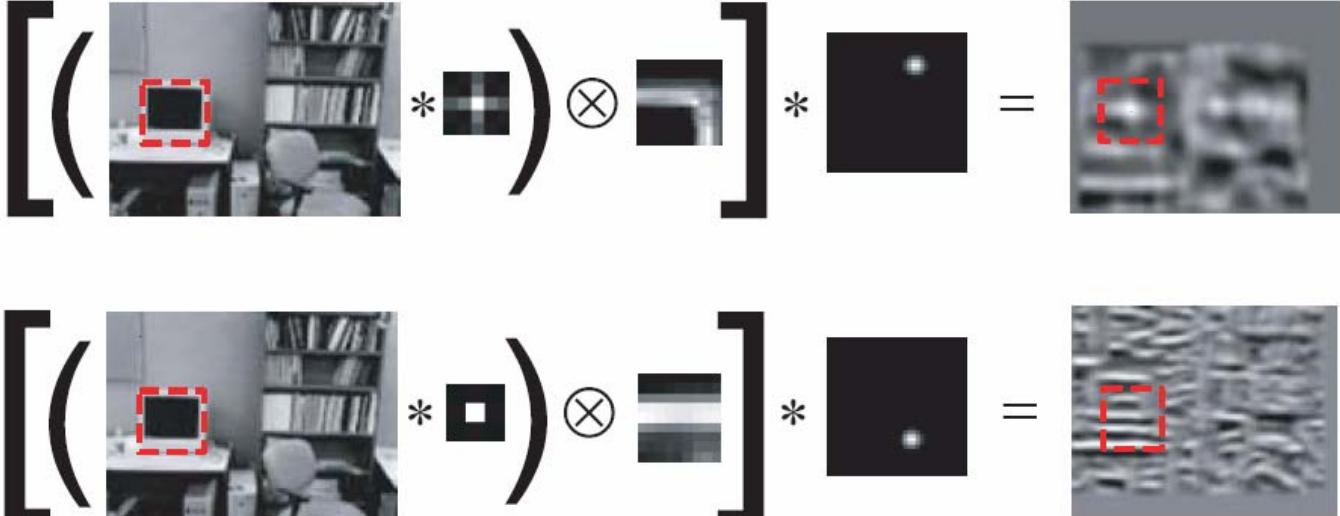

Weak detectors

We can do a better job using filtered images

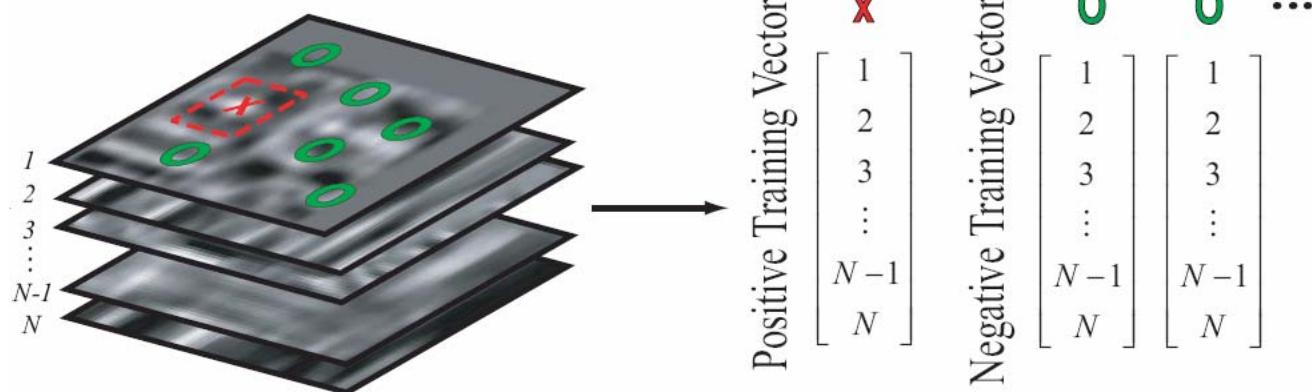

Training

First we evaluate all the N features on all the training images.

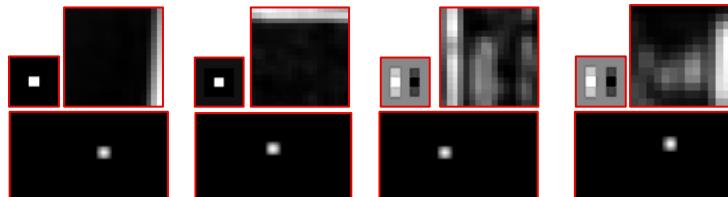

$$\begin{array}{l} \text{Feature 1} \\ \vdots \\ \text{Feature } N \end{array} \quad \left[\left(\text{Image} \left[\begin{array}{c} \text{Red Box} \\ \text{Object Center} \end{array} \right] * \text{Feature Map} \right) \otimes \text{Mask} \right] * \text{Response Map} = \text{Output Image} \quad || \quad \left[\left(\text{Image} \left[\begin{array}{c} \text{Red Box} \\ \text{Background} \end{array} \right] * \text{Feature Map} \right) \otimes \text{Mask} \right] * \text{Response Map} = \text{Output Image}$$

Then, we sample the feature outputs on the object center and at random locations in the background:

Face-hunting cameras boost Nikon

Japanese camera maker Nikon has tripled its profits on the back of strong sales of digital cameras that automatically focus on human faces.

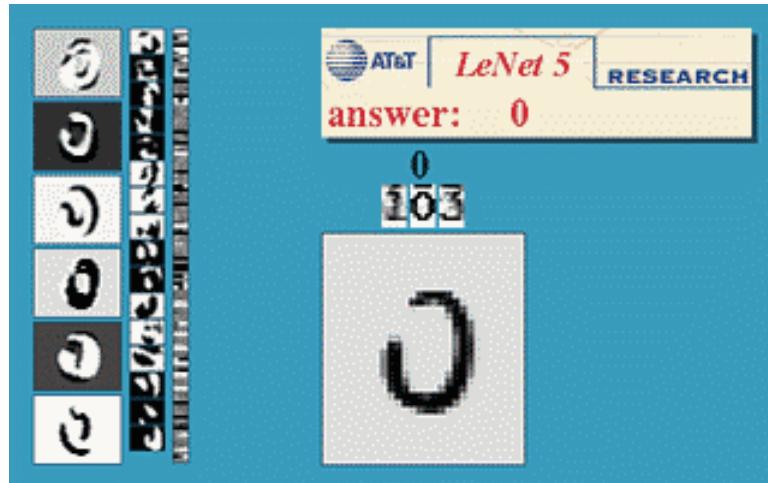

Face recognition cameras like the Coolpix L1 are popular

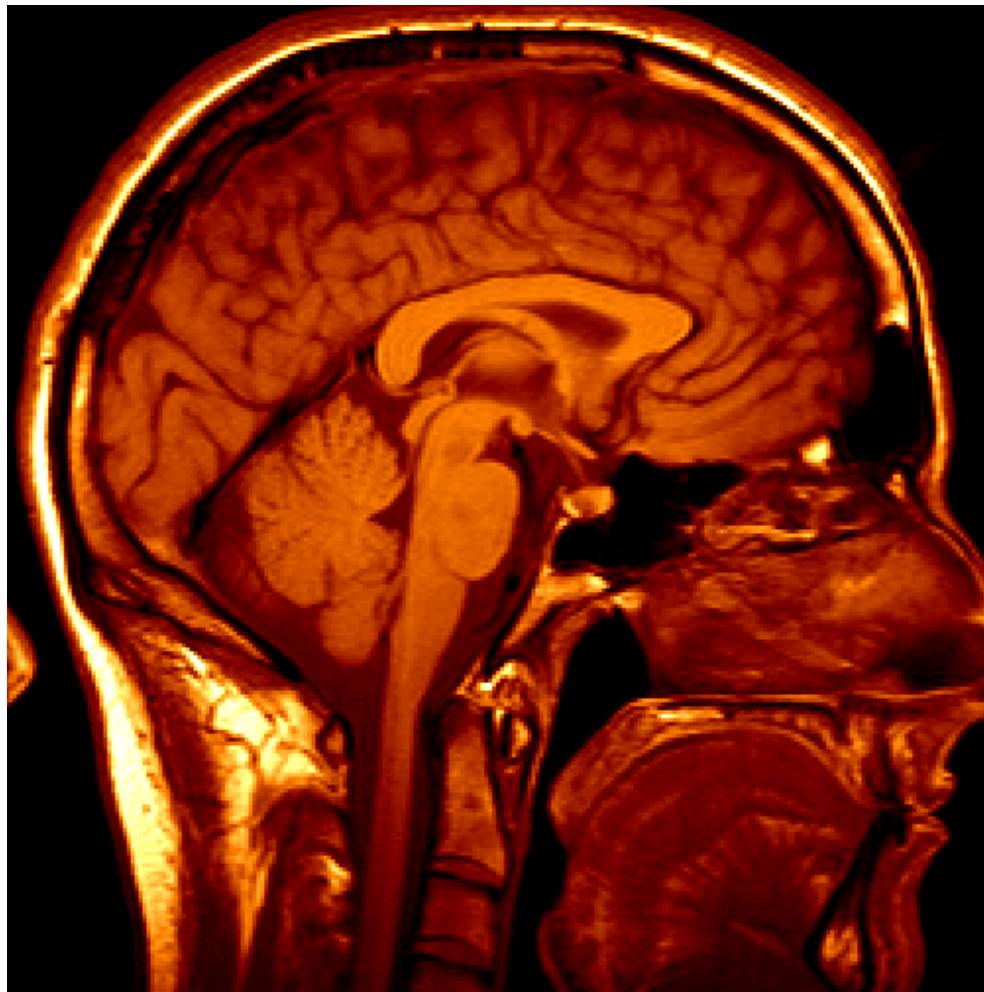

Sample image: Subject as seen on the COOLPIX 5900 camera's color LCD and when using Nikon's Face-priority AF function.
